parallel to Saturn's magnetic field for both the A and B viewing locations. Thus, the SKR RH beam seems to emanate from the northern hemisphere in the sector containing A and B, and oriented more towards A.

We can speculate on the source location by making some assumptions concerning the shape and orientation of the SKR beam. The Earth's AKR beam near the frequency of peak flux

density is very broad, closely resembling a cosine pattern with the beam axis oriented more or less parallel to the field15. If we assume that SKR is also emitted in a broad, symmetrical beam pattern, and that the axis of the pattern is also oriented parallel to the field, we can determine where the axis must be in local time and latitude so that intensities received at A exceed those at B by some factor consistent with Table 1. Figure 5 shows a plot similar to Fig. 1 indicating the locus of possible beam axes for three different broad beams where A would receive 2-4 times as much flux as B. The calculations were made at altitudes corresponding to 175-kHz electron gyrofrequency. The field lines yielding solutions were then traced to the surface (invariant latitude). Several source locations are possible, but most intriguing is the region at high latitudes near the noon meridian. This region most likely corresponds to the auroral zone 9.16, and, by analogy with the Earth² and Jupiter⁶, is a very good candidate for a region of enhanced particle precipitation required to produce radio emission. Additionally, the apparent confinement of the radio source to a limited dayside range of local times suggests an association with a dayside polar cusp in Saturn's magnetosphere17. Because SKR is fixed in local time, we can equate local time and sub-solar SLS as shown at the top of Fig. 5. The SLS corresponding to the proposed source region (40°-145°) may correspond to a region of anomalous magnetic field, although it is not clear that a precipitation producing field anomaly need be in the source region itself. The Voyager 1 close approach to Saturn was at high southern latitudes and displaced some 90-100° in longitude from the proposed source location, so fields and particle experiments were not able to make measurements on field lines threading this region. However, the Voyager 2 close approach on 25 August 1981 will be in a much better position to make measurements over this region.

emissions Narrowband electromagnetic from Saturn's magnetosphere

D. A. Gurnett*, W. S. Kurth* & F. L. Scarf*

*Department of Physics and Astronomy, The University of Iowa, Iowa City, Iowa 52242, USA †TRW Defense and Space Systems, One Space Park, Redondo Beach, California 90278, USA

A series of narrowband electromagnetic emissions were detected by the plasma wave instrument on board Voyager 1 coming from the inner region of Saturn's magnetosphere in the frequency range 3-30 kHz. These emissions have many similarities to continuum radiation detected in the Earth's magnetosphere and narrowband kilometric radiation in the jovian magnetosphere. The observed frequency spacing suggests that the emissions are being generated near Tethys, Dione and Rhea, probably in regions of large plasma density gradients associated with boundaries of the plasma sheet.

During the Saturn flyby the Voyager 1 plasma wave instrument observed a series of narrowband electromagnetic emissions at frequencies between 3 and 30 kHz (ref. 1). These bands are remarkable because of their extremely complex spectral structure, consisting of a large number of nearly monochromatic emissions with frequency spacings corresponding to the equatorial electron gyrofrequencies near the moons Tethys, Dione and Rhea. Because of the possible association of the radio emissions with the moons of Saturn, we have analysed these emissions to determine their origin and to explore similarities to other planetary radio emissions. We describe here their characteristic and discuss models of the generation of these emissions (the plasma wave instrumentation is described in ref. 2).

Observations

The strongest and best resolved examples of the narrowband electromagnetic emissions occur in the inner region of the magnetosphere, near closest approach. The electric field intensities in this region are shown in Fig. 1. Each channel gives the electric field intensity on a logarithmic frequency scale at the centre frequencies indicated on the left of the plot. The electron gyrofrequency, f_g , and plasma frequency, f_p , are also shown for reference. The electron gyrofrequency $(f_g = 28B \text{ Hz}, \text{ where } B \text{ is})$ the magnetic field in nT) was determined from the Voyager 1 magnetic field instrument³, and the plasma frequency $(f_p =$ $9,000 \sqrt{n_e}$ Hz, where n_e is the electron number density cm⁻³) was obtained from the Voyager 1 plasma instrument⁴. The narrow-

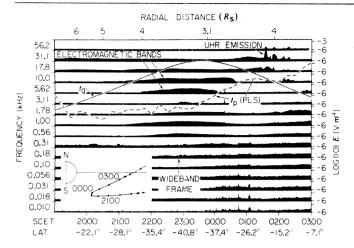

Fig. 1 The plasma wave electric field intensities in the region near closest approach. The narrowband electromagnetic emissions are confined to the low density region outside of the plasma sheet at $f > f_p$ (dashed lines). The plasma sheet is entered at about 00.00 to 01.00, as the spacecraft approaches the magnetic equator (see trajectory sketch).

band electromagnetic emissions consist of a series of smooth enhancements in the 3.11–31.1-kHz channels from about 21 h 00 min (spacecraft event time) on 12 November to 01 h 00 min on 13 November. These enhancements all occur at frequencies above the electron plasma frequency as determined by the plasma experiment. The sharp cutoffs evident in the 5.62- and 10.0-kHz channels shortly after closest approach seem to be directly associated with the local electron plasma frequency. The enhanced intensities extend across the electron gyrofrequency with no obvious propagation effect. These characteristics identify the mode of propagation as the free-space left-hand polarized ordinary (L,0) mode. For this mode propagation occurs for all frequencies $f > f_p$, and that no resonance or cutoff occurs at the electron gyrofrequency.

Another type of very intense narrowband emission occurs in the 31.1-kHz channel of Fig. 1 at about 01.30 on 13 November, coincident with the cutoff of the electromagnetic radiation. At peak intensity this narrowband burst has a field strength ~ 60 db larger than the adjacent radiation. Based on similar observations in the Earth's magnetosphere ⁵⁻⁷ and at Jupiter ⁸⁻¹⁰ this burst is identified as an electrostatic emission at the local upperhybrid resonance (UHR) frequency, $f_{\rm UHR} = (f_p^2 + f_g^2)^{1/2}$. The fact that the observed emission frequency is higher than the upper hybrid resonance frequency computed from the measured plasma frequency and gyrofrequency is attributed to uncertainties in the determination of the electron number density. The electron plasma frequency is a factor of ~ 3 higher than given by the plasma instrument at this particular time.

Because the intensity of the electromagnetic radiation is comparable in adjacent frequency channels, Fig. 1 implies that the spectrum is nearly continuous, possibly comparable with the continuum radiation detected in the Earth's magnetosphere⁵. Fortunately, one 48-s frame of wideband waveform data obtained in this region provides greatly improved frequency resolution. The high-resolution spectrum of the wideband data (Fig. 2) is not continuous, but rather consists of many narrowband emissions, some with bandwidths < 100 Hz. Three main bands can be identified at frequencies of ~1 kHz, ~6 kHz, and ~9.7 kHz. Because the low-frequency band at 1 kHz is below the electron plasma frequency, whereas the others are all above it, this band cannot be propagating in the same mode as the higher frequency bands. For $f < f_p$ the only possible modes are the whistler-mode and the z-mode. Based on the similarity to whistler-mode hiss emissions observed in the higher density regions of the plasma sheet, we concluded that this lowfrequency (~1 kHz) band is propagating in the whistler mode1.

The most definitive evidence that the high-frequency bands are propagating in the free-space electromagnetic mode is given in Fig. 3, which shows a series of wideband spectrograms

obtained over a 3-day period near and after closest approach. A single persistent band of emission can be seen at ~5 kHz extending over a range of radial distances from at least 3.26 to $58.3 R_{\rm S}$. Because the plasma parameters change over a wide range it is difficult to see how this band of emission could be observed over such a large range of radial distance without being a freely propagating electromagnetic wave. The last observation, Fig. 3 F, is in the magnetosheath where the local plasma frequency is ~3.8 kHz [J. Scudder, personal communication]. Although the electromagnetic bands can be detected in the wideband data over several days, the intensity and detectability vary considerably. The meridian plane plot in Fig. 4 summarizes the regions in which the bands were detected. Except for the brief interval near closest approach all of the emissions were confined to high latitudes on the outbound pass. None were found on the inbound leg and this is almost certainly due to the fact that the spacecraft was passing through the high density central region of the plasma sheet where the electron density is high enough to refract the radiation away from the equatorial region. In contrast, for the outbound pass $(R \ge 10 R_s)$ at high latitudes the electron density4 is always low enough to allow direct line-of-sight propagation to the spacecraft at frequencies above a few kHz. The strongest emissions were observed at position A near closest approach, suggesting that the radiation originates in the inner region of the magnetosphere at $R \leq$ $10 R_s$

Examination of the 16-channel survey plots shows evidence of a periodic modulation of the narrowband emission intensities at the 10 h 40 min rotation period of Saturn. Typically, the narrowband emission events last for ~ 3 or 4 h and tend to recur at intervals of ~ 11 h. The three intervals containing B, C-D, and E, in Fig. 4 show this periodicity. Maximum intensity occurs when the Saturn longitude system (SLS) longitude of the subsatellite point is near 290°. Event F in Fig. 4 is also in phase with this general rotational modulation, however, one cycle seems to have been missed between E and F, possibly owing to the very low intensity and difficulty of detecting these emissions far from the planet.

Relationship to other planetary radio emissions

Although the complex narrowband structure of these Saturn radio emissions appears unusual, very similar types of radio emissions have been identified in the magnetospheres of Earth and Jupiter. At Earth a relatively weak type of broadband radio emission called continuum radiation is generated within the magnetospere ^{5,11,12}. This has a relatively smooth steady temporal structure, and when analysed with spectral resolution comparable with that of the Voyager 16-channel analyser, the

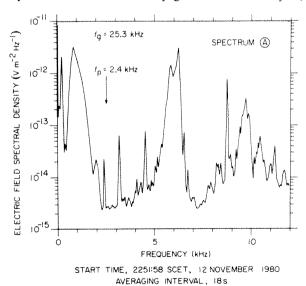

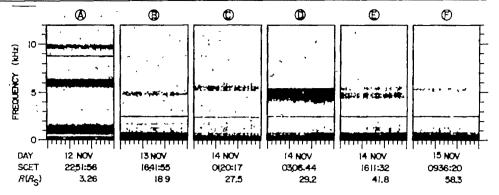

Fig. 2 A detailed frequency spectrum of the emission in Fig. 1, showing the occurrence of numerous bands with approximately harmonic frequency spacings.

Fig. 3 Prequency-time spectrograms obtained in various regions of the magnetosphere demonstrating that the band at ~5-6 kHz can be detected over a large range of radial distances. This series of observations provides the best evidence that the noise consists of freely propagating electromagnetic radiation.

overall appearance is very similar to the emissions shown in Fig. 1. When the terrestrial continuum radiation is analysed with better frequency resolution it becomes apparent that the spectrum is not continuous, but instead consists of a series of discrete narrowband emissions¹³. The detailed characteristics of the continuum spectrum depend on the frequency range. At frequencies below the solar wind plasma frequency, where the radiation is trapped in the low-density magnetospheric cavity, the spectrum tends to be nearly continuous with only occasional narrowband structure¹¹. At frequencies above the solar wind plasma frequency, where the radiation can freely escape from

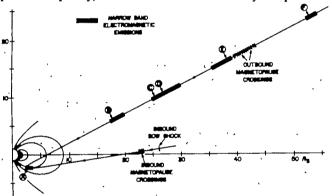

Fig. 4 A summary of regions where narrowband electromagnetic emissions were observed. The black bands indicate detections in the 16-channel spectrum analyser data, and the circles correspond to the wideband spectrograms shown in Fig. 3.

the magnetosphere, the frequency spectrum usually shows considerable narrowband structure. Typically, it consists of several relatively broad emission bands consisting of numerous narrowband features, some of which have harmonic frequency spacings.¹³ The spectral characteristics of the terrestrial narrowband emissions are remarkably similar to those observed at Saturn

At Jupiter narrowband electromagnetic emissions (narrowband kilometric radiation (nKOM)) with similar characteristics have been reported by Kaiser and Desch¹⁴. Although the frequency resolution available for the jovian nKOM observations is not sufficient to reveal the extraordinary fine structure evident in the terrestrial and saturnian emissions, the overall characteristics are quite similar. In particular, the jovian nKOM intensity is controlled by the rotation of Jupiter, very similar to the rotational control of the narrow-band emissions observed at Saturn. The period of the nKOM is slightly slower than the rotation period of Jupiter, and corresponds to the rotation period of the plasma in the outer region of the Io plasma torus¹⁴, at a radial distance of about $10\ R_J$.

The close similarities between the narrowband electromagnetic emissions at Earth, Jupiter, and Saturn strongly suggest that the same basic emission mechanism operates at all three planets. At Earth it is now widely believed that continuum radiation is generated by mode conversion from electrostatic waves generated by low-energy electrons. This general mechanism has a long history of experimental and theoretical development 5.7,15,16, including the observation of enhanced radiation intensities when low-energy electrons are injected into

the magnetosphere¹⁷. The electrostatic wave involved is an electrostatic mode which occurs near the upper hybrid resonance frequency, $f_{\rm UHR} = (f_{\rm p}^2 + f_{\rm g}^2)^{1/2}$. One of the specific conditions which must be satisfied for this mode to be unstable is that $(n+1/2)f_s \simeq f_{UHR}$ (refs 6, 7, 18). The physical situation in the Earth's magnetosphere is illustrated in Fig. 5, which shows a representative radial profile of f_{UHR} and f_g near the plasmapause. Intense electrostatic emissions occur whenever f_{UHR} crosses a half-integral harmonic of f_s (dashed lines). Kurth et al. 13 have demonstrated that the electrostatic emissions are directly converted to electromagnetic radiation with little or no frequency shift. The radiation is generated in the free space (L, 0) mode. The resulting radio emission spectrum therefore consists of a series of lines with a frequency spacing characteristic of the electron gyrofrequency in the source region. Kurth et al. 13 have proposed that the jovian nKOM radiation can be explained by essentially the same mechanism, with the density gradient in the outer region of the Io plasma torus having the same role as the plasmapause at Earth. Large plasma density gradients are an essential element of some theories for the electrostatic to electromagnetic mode conversion¹⁹.

Interpretation of Saturn observations

Because of the close similarities between the narrowband radio emissions at Earth, Jupiter and Saturn, the electrostatic to electromagnetic mode conversion mechanism probably also accounts for the narrowband emissions at Saturn. This view is supported by the fact that intense upper hybrid waves are observed at Saturn in the region where the narrowband electromagnetic radiation is most intense (see Fig. 1). Also, at Saturn these emissions are known to be propagating in the free space (L, 0) mode—the favoured mode for mode conversion. But the exact source location and the physical processes which lead to the generation of intense electrostatic waves remain uncertain.

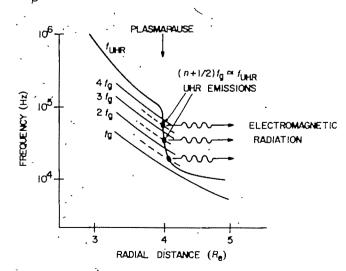

Fig. 5 A model illustrating the mechanism for generating narrowband electromagnetic emissions (continuum radiation) in the Earth's magnetosphere. Intense electrostatic upper hybrid resonance (UHR) emissions at $(n+1/2)f_a \simeq f_{\rm LHR}$ are believed to be converted to electromagnetic emissions in regions with steep plasma density gradients, such as near the plasmapause

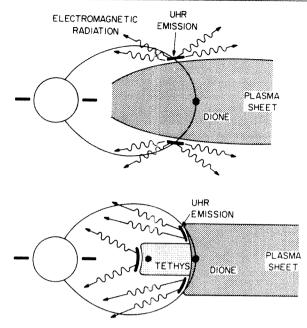

Fig. 6 Two possible models for generating narrowband electromagnetic emissions in Saturn's magnetosphere. a, The emissions are generated at the density gradient which exists at the north and south boundaries of the plasma sheet; b, the emissions are generated along the field-aligned boundaries of the plasma sheet.

Unfortunately, because of no appreciable tilt in the magnetic dipole axis of Saturn, there are no geometry-dependent propagation effects to help determine the source location. Probably the best clue is the frequency spectrum. If the mode conversion model is correct then the frequency spacing between the lines is approximately the electron gyrofrequency in the source region. Figure 2 shows that several half-integral harmonic frequency spacings can be identified in the radio emission spectrum. If we identify the main emissions at 6.0 and 9.7 kHz as a harmonic pair, then the gyrofrequency is 3.7 kHz. A second set of lines can be identified at 3.1, 4.7 and 6.1 kHz, which gives a gyrofrequency of 1.50 kHz. Finally, a third set of lines at 8.7, 9.6, 10.4 and 11.4 kHz gives a gyrofrequency of 870 Hz. Assuming that the source is located near the equatorial plane (as at Earth and Jupiter) the corresponding radial distances for these gyrofrequencies are 5.4, 7.3 and 8.8 Rs. based on a dipole moment of 0.21 G R_s^3 (ref. 3). Note that depending on the plasma density gradient in the source region and the location of the source relative to the magnetic equator, the observed emission frequencies may not occur at exact halfintegral harmonics. Therefore, these radial distances should be regarded as only a rough indication of the source position. The radial distances obtained are in the vicinity of Tethys, Dione and Rhea. Because at least one of Saturn's moons, Dione, is already thought to have an important role in controlling Saturn's kilometric radio emissions 1,20,21, this comparison strongly suggests that one or more of these moons is involved in generating the narrowband electromagnetic emissions.

The most likely way a moon could control nonthermal radio emission processes in the inner region of Saturn's magnetosphere is by injecting plasma much as Io controls radio emissions by injecting plasma into the jovian magnetosphere. Evidence from the Pioneer 11 and Voyager 1 plasma instruments^{4,22} suggests that plasma production by Tethys and Dione may be the source of the extended disk-shaped plasma sheet observed near the equatorial plane of Saturn. If nonequilibrium processes associated with the plasma injection are responsible for the narrowband electromagnetic emissions, then the analogies with Earth and Jupiter would suggest that the source is associated with a steep plasma density gradient near the edge of the plasma sheet. Figure 6a, b shows two extreme models for the source positions. In Fig. 6a the source is located near the north-south boundaries of the plasma sheet, and in Fig. 6b near the sharp

field-aligned inner boundary of the plasma sheet described by Bridge et al.4.

If the source is located as in Fig. 6a then it would have to be tightly confined to a specific L-shell to produce the narrow emission spectrum. Such a localization could, for example, be caused by a field-aligned current system flowing along the Dione L-shell. A source located on the Dione L-shell at the northsouth boundary of the plasma sheet $2 R_s$ from the equatorial plane would have an electron gyrofrequency in close agreement with the 3.7-kHz major frequency spacing evident in Fig. 2. On the other hand, if the source is located along a field-aligned inner boundary of the plasma sheet then the narrowband characteristic of the source would be easily explained as the gyrofrequency is, to first order, constant along the magnetic field line near the equator. This situation could be closely analogous to the generation of continuum radiation near the plasmapause at the Earth, except that the decreasing density gradient is facing towards rather than away from the planet. Note that the 7.3 R_s radial distance identified for the 1.5 kHz frequency spacing in Fig. 3 closely agrees with field-aligned boundary identified by Bridge et al. 4 at L = 7. This boundary occurs slightly beyond the orbit of Dione. Because of uncertainties concerning the plasma density distribution in the inner region of the magnetosphere, it is too early to decide which can best account for the characteristics of these emissions.

Conclusion

The Voyager 1 flyby of Saturn has revealed narrowband electromagnetic emissions originating from the inner region of the magnetosphere. At closest approach the broadband electric field strength of these emissions is $\sim\!50~\mu V~m^{-1}$, which corresponds to a total radiated power of about $2.5\times10^6~W$, assuming an isotropic source. Although this is small compared with the power radiated by Saturn at kilometric wavelengths, $\sim\!10^8-10^9~W$ (ref. 20), these emissions are of interest because of the close similarity to narrowband radio emissions from Earth and Jupiter.

Comparisons with similar emissions in the Earth's magnetosphere suggest that they are produced by mode conversion from electrostatic waves near the upper hybrid resonance. This radio emission mechanism has also been proposed to explain certain types of solar radio emissions2. Although the basic mechanism has been identified, the conditions in which the radiation can occur are poorly understood. Observations at all three planets suggest that distinct 'hot spots' occur from which the radiation is preferentially emitted. The association of the source with a plasma density gradient may be a requirement for the mode conversion process¹⁹. Unfortunately, the requirements for generating the electrostatic waves are not completely understood. The generation of these waves probably involves the presence of large fluxes of low energy (100 eV to 1 keV) electrons with a pronounced loss-cone or $\partial f/\partial v_{\perp} > 0$ feature and a suitably large cold-to-hot electron density ratio 18,24,25 The apparent control of the narrowband emission intensities by Saturn's rotation presumably provides an important clue to the processes involved. However, because of the very close alignment of the dipole axis with the rotational axis of Saturn³, it is not clear how this rotational control is imposed.

Finally, at Saturn no evidence was found for trapped continuum radiation comparable to the continuum radiation trapped in the low density magnetospheric cavity of Earth and Jupiter. As the Voyager 1 plasma measurements⁴ demonstrate the existence of a low-density cavity at Saturn with an electron plasma frequency well below the solar wind plasma frequency, it is surprising that no radiation is trapped in this cavity. The radio emission source at Saturn does not seem to extend down to sufficiently low frequencies to illuminate the cavity. The reasons for this marked difference in the radio emission spectrum are not understood.

Saturn's radio emissions: rotational modulation

C. K. Goertz*†, M. F. Thomsen*‡ & W.-H. Ip*

*Max-Planck-Institut für Aeronomie, 3411 Katlenburg-Lindau 3, FRG †Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52240, USA ‡Los Alamos Scientific Laboratory, Los Alamos, New Mexico, 87545, USA

The unexpected rotational modulation of the Saturn kilometric radiation and Saturn electrostatic discharges, as revealed by Voyager 1 observations, are discussed in terms of a ring-current system and the geometry of the dipole field.

THE Saturn flyby observations of Pioneer 11 and Voyager 1 have revealed that the Saturnian ring system has important effects on the structures of the planetary ionosphere as well as the magnetospheric environment, such as the unexpected rotational modulation of the Saturn kilometric radiation (SKR) and the Saturn electrostatic discharge (SED) as discovered by the Voyager planetary radio astronomy experiment¹. The emissions of the bursty and highly polarized SKR (f < 1,200 kHz) and the broad banded and unpolarized SED ($f \sim 20.4 \text{ kHz}-40.2 \text{ MHz}$) of impulsive nature strongly peaks at the subsolar longitude (SLS) of ~110°. The rotational control of the SKR and SED is a clock-like effect-with radiations preferentially emitted when Saturn has a particular phase relative to the Sun 1,2. Although the sources of these radio emissions are not clear, Warwick et al.1 argued that the SED emissions most likely originate in the rings of Saturn.

The challenge then is to devise a mechanism which can produce electrodynamic coupling between the ring system and the planetary ionosphere and/or magnetosphere in which the associated SKR and SED radio emissions are subject to longitudinal control. One obvious candidate is the establishment of field-aligned current systems—connecting the rings and the ionosphere with longitudinal variation. Local acceleration processes in the vicinity of the rings are also needed. Although the solution will probably have to await further observations and more detailed data analyses, we now discuss the interplay between the ring-current systems and the geometry of the dipole field and the rings and describe some of the basic ingredients in the longitudinal modulations of SKR and SED.

The Pioneer 11 radio measurements³ and the Voyager 1 EUV experimental results⁴ reveal that a strong coupling between the neutral hydrogen atmosphere of the rings with a number density of 400-600 cm⁻³ (refs 4-7) and the ionospheric plasma. Assuming the ionospheric H⁺ ions have a number density of $n_i \sim 3 \times 10^3$ cm⁻³ near the ring plane, the pertinent chargeexchange loss time scale for the neutral H atoms can be estimated to be $\sim 10^6$ s. Thus, for a total volume of the ring atmosphere to be $\sim 3 \times 10^{30}$ cm³, the charge-exchange loss rate of the neutral atoms as a result of the $H^+ + H \rightarrow H + H^+$ process is $\dot{N} \sim 10^{27} \, \mathrm{s}^{-1}$. This value is perhaps the most direct estimate for the source strength of the ring atmosphere and it supports the assessment by Carlson⁸ that photo-sputtering of atomic hydrogen atoms from H₂O ice on the ring particles is responsible for supplying the observed H cloud of the rings, as other proposed effects9.10 are far less efficient.

Note that the acceleration of the new ions (from charge exchange and other ionization effects) to co-rotation with the

magnetosphere will necessitate the establishment of a so-called pickup current which flows radially outward outside the synchronous orbit (at 1.8 R_s) but inward inside this distance^{11,12}. An order-of-magnitude approximation can be obtained by using $I \sim \dot{M} \Delta v / B \Delta x$ for the total current. Here \dot{M} is the mass addition rate. B is the average magnetic field ($\sim 2,500 \text{ nT}$), $\Delta v \sim$ 1 km s⁻¹ is the difference between the corotating speed and the keplerian orbital speed, and Δx is the characteristic radial dimension of such a ring-current system. Even when the ionization rate of oxygen atoms is set equal to that of neutral H atoms, $I \le 10^3$ A for $\Delta x \sim 1 R_s$. This pickup current system is therefore relatively small, and not subject to rotational modula-

Another current system is more promising. The near-perfect dipole field of Saturn has a slight vertical displacement (h) of the dipole centre from the planet's centre along the axial direction 13-15. This enables charged particles to mirror just above the ring plane without being absorbed—a sort of plasma disk may be formed there. The longitudinal drifts (due to magnetic curvature force, gravity etc.) of the ions and electrons in this region would

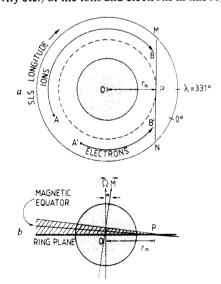

Fig. 1 a. Top view of the intersection between saturnian rings and the magnetic equator. The two planes intersect at \overline{MN} and $\overline{OP} = 1.64 R_s$ if the vertical displacement is $0.02 R_s$ and the tilt angle α is 0.7°. Inside the synchronous orbit r_{syn} at 1.8 R_s the ions drift west $(A \rightarrow B)$ and electrons east $(A' \rightarrow B')$. Beyond r_{syn} they move in opposite directions. b, Side view of the above system. Particles with near 90° equatorial pitch-angle in the wedgeshaped 'free-zone' are not subject to any absorption.

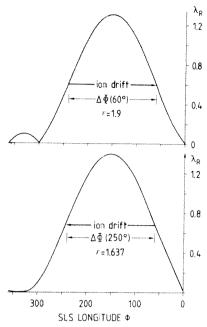

Fig. 2 The magnetic latitudes λ_r of the ring for h=0.02 and $\alpha=0.7^\circ$ for two radial distances: a, r=1.9 R_s ; b, r=1.64 R_s . Also indicated are longitudinal ranges of ions between ionization and ring absorption.

then constitute a current flowing in the azimuthal direction. At the same time, there is also a small tilt (α) of the dipole axis with respect to the spin axis of Saturn towards SLS longitude 331° (ref. 15). The important feature is that the magnetic equatorial plane and the ring plane intersect along a line which has its minimum distance from Saturn (r_m) at an SLS longitude of 331°. For $\alpha = 0.7^{\circ}$ and an offset of $h = 0.02 R_{\rm S}$ (refs 13-15), $r_{\rm m} =$ 1.64 R_s . This combination of the vertical displacement and the tilt would cause the azimuthal currents to be interrupted at certain positions in the rings for $r > r_m$ (see Fig. 1). (For $r < r_m$ the magnetic latitude of the ring plane is always non-zero and some charged particles will therefore escape absorption by the rings. This disk-population may suffer from pitch-angle scattering through wave-particle interactions and become unstable.) Assuming that the mirror-latitudes of the ions do not change over a time scale of one longitudinal drift around the planet, their drift paths $(r\Delta\Phi)$ can be determined by the difference between magnetic latitude (λ_r) of the ring plane and their mirror-latitudes (λ_m) . Once the charged particles drift into the region with $\lambda_m > \lambda_r$, they would be absorbed. The variations of $\Delta \Phi$ for two radial distances are sketched in Fig. 2.

Assuming current continuity $(\nabla \cdot j = 0)$, the longitudinal variation of the azimuthal current (j_{\perp}) due to the mirroring effect would mean continuous diversion of the currents into the field-aligned components (j_{\parallel}) . To estimate the field-aligned current at different longitudes (ϕ) the following relations are needed. First, the current continuity equation can be written as

$$j_{\parallel} = -\frac{1}{r} \frac{\partial}{\partial \phi} \int j_{\perp} \, \mathrm{d}z \tag{1}$$

and second, the continuity equation for mirroring particles as

$$\frac{1}{r} \frac{\partial}{\partial \phi} (n_i v_d) = \frac{n_H}{\tau_i} - L_i$$
 (2)

with $j_{\perp} \approx n_i e v_d$ where n_i is the ion number density at longitude ϕ , v_d is the drift velocity¹⁶, n_H is the neutral H atom number density of the ring atmosphere (say), τ_i the ionization time scale and L_i the loss rate. Assuming that the ions can only mirror along the field lines in the region where $\lambda_i > \lambda_m$,

$$n_{\rm i} \sim n_{\rm H} \left(\frac{\tau_{\rm d}}{\tau_{\rm e}}\right)$$
 (3)

where the longitudinal drift time scale between ionization and absorption is $\tau_d = r\Delta\Phi(\phi)/v_d$. Combining these relations, the field-aligned current density at longitude ϕ can be written as:

$$j_{\parallel}(\phi) \sim er \frac{\partial}{\partial \phi} \int_{0}^{\lambda_{r}(\phi)} \frac{n_{H}}{\tau_{i}} \Delta \Phi(\phi) d\lambda$$
 (4)

Note that in the corotating system $\Delta\Phi > 0$ if ions drift westwards towards increasing SLS longitudes (inside the synchronous orbit) and $\Delta\Phi < 0$ if ions drift in the opposite direction (outside the synchronous orbit).

Contour plots of the field-aligned current density (j_{\parallel}) inside the synchronous orbit are shown in Fig. 3. Two maxima are found at SLS longitudes 120° (upward current from ionosphere to the ring) and 250° (downward current from the ring to ionosphere). Such field-aligned currents are corotating with the planet and if the ionization rate in this system is subject to diurnal variation, rotational modulation may conceivably result. For example, the escape flux of the ionospheric electrons reaching the ring at L=1.6 may have large day-night variation due to absence of photoelectron emission and cooling of the exosphere in the night side. (Note that an important nightside heat source, precipitation of energetic particles, does not exist at the latitudes magnetically connected to the rings as the rings are extremely good absorbers of energetic charged particles.)

But note that the azimuthal currents and the associated field-aligned components would be maintained, to a certain degree, even in the shadow of Saturn. This is because the ions produced in the dayside would continue to drift into the shadow to replenish the drift currents. The actual ionization rate must be largely determined by charge exchange between the neutral ring atmosphere and the planetary ionosphere as photoionization and electron impact ionization all have very long ionization time scales ($\geq 10^9$ s). Using the minimum value of $\tau_i \sim 10^6$ s as appropriate for regions a fraction of a planetary radius from the ring plane, and a number density of 500 cm⁻³ for the hydrogen atoms) the peak flux (at SLS longitude 250°) can be estimated as $F_{\parallel} \sim 10^6 \text{ cm}^{-2} \text{ s}^{-1}$ in the equator and $10^7 \text{ cm}^{-2} \text{ s}^{-1}$ near the top of the saturnian ionosphere. This is larger than the estimated photoelectron flux of 2×10^5 cm⁻² s⁻¹ from Saturn's ionosphere 10. Thus the downward field-aligned current near SLS longitude 250° could become supercritical, particularly when it moves into Saturn's shadow. In such conditions, an electric field parallel to the magnetic field must be set up accelerating the ionospheric electrons away to maintain the downward current. The parallel potential drop could reach an absolute maximum equal to the total potential drop ψ across the current generating region.¹⁷ This potential ψ arises from the fact that the fieldaligned currents must close through the saturnian ionosphere which has a finite conductivity. According to Hill et al. 18 the total

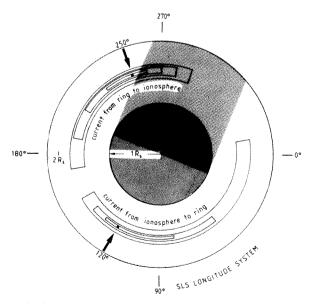

Fig. 3 Contour plot for the parallel electron flux (inside the synchronous orbit) associated with the field-aligned current system. Note that maximum flux from ionosphere to the ring occurs at SLS longitude 250° and the maximum flux from the ring to the ionosphere occurs at 120° SLS longitude.

potential drop across the longitude range $\Delta\Phi$ is

$$\psi = \frac{r\Delta\Phi}{\Sigma_{\rm p}} \int j_{\perp} \, \mathrm{d}z = \frac{I}{\Sigma_{\rm p}} \frac{r\Delta\Phi}{\Delta r}$$
 (5)

Here Δr is the radial range of the field-aligned currents at radial distance r, $\Delta \Phi$ is the corresponding longitude range and Σ_p is the height-integrated Pederson conductivity of the planetary ionosphere. With the total current going through the ring system estimated to be $\sim 10^4 - 10^5 \,\text{A}$, $\Delta \Phi \sim \pi$, $r \sim 1.5 \,R_J$ and $\Delta r \sim$ 0.3 R_1 ; $\psi = (0.15-1.5)/\Sigma_p$ (MV). Because Σ_p should be of the order of 1 S, if not less, the parallel potentials are conceivably quite large, that is of the order of a few keV.

Although the incorporation of SKR and SED radio emissions into this scheme is tempting but ambiguous a plausible scenario is offered below. We assume that a parallel potential of a few keV could be established in the shadow at SLS longitude 250° and that the ring particles are charged up to electrostatic potential of similar magnitude by the energetic electrons so generated. As soon as the ring particles move into the sunlight there will be immediate electrostatic discharge through emission of photoelectrons (accelerated to keV energies by the negative surface potential)¹⁹. The electrostatic energy stored on a 1-m radius ring particle charged to 10 keV is 10^{-2} J . Assuming no surface resistance the discharge time would be $\tau \sim 4 \times 10^{-8} \text{ s}$. The total

power emitted by each ring particle is 2.5×10^5 W and should be broadband extending to a frequency of roughly $1/\tau \sim 25$ MHz. The maximum intensity of SED should then occur when the spot at SLS longitude 250° emerges from the shadow at which time the SLS longitude 110° faces the Sun (see Fig. 3). This is almost exactly the longitude at which the SED and SKR activities peak. (It is not clear whether the formation of radial spokes in the B ring as observed by the Voyager Imaging experiment²⁰ is related to this effect.)

SKR events still have to be explained and to a certain extent SKR may also depend on the SED. That is, as the broadband and bursty SED radiation propagates outwards, it will be absorbed by the dense plasma sheet between 4 and 8 R_s (refs 20, 21). If pitch-angle scattering of trapped energetic particles into the atmospheric loss cone is enhanced by plasma wave absorption, rotational modulation of SKR (in the desired manner) would follow. As there are sharp rises in the proton $(E_p <$ 2 MeV) and electron (E_e <0.43 MeV) fluxes near the orbit of Dione²², precipitation events triggered by the SED radiation must involve principally particles from that region. It is perhaps no great surprise that the SKR emission—besides the 10-h rotational modulation—also seems to be affected by Dione².

Saturn's kilometric radiation: satellite modulation

M. D. Desch & M. L. Kaiser

NASA/Goddard Space Flight Center, Laboratory for Extraterrestrial Physics, Planetary Magnetospheres Branch, Greenbelt, Maryland 20770, USA

There is an episodic 66-h modulation of the Saturn kilometric radiation which is both frequency and Dione-phase dependent. The behaviour is significantly different from the way in which Io modulates the jovian emission.

THE discovery¹ of nonthermal (kilometric) radio emission (SKR) from Saturn by the Voyager planetary radio astronomy (PRA) instrument has raised the possibility of emission modulation by one or more of its satellites because Saturn, like Jupiter, contains satellites deep within a corotating magnetic field. However, examination of data extending from January to September 1980, yielded no Saturn analogue of the well-known Io-control phenomenon². Instead, short-term (10 day) modulation of the SKR has been reported^{3,4} at a period near 66 h, thus implicating satellite Dione as a possible agent. The nature of this modulation, if real, differs dramatically from the way in which Io controls the jovian emission. Using the PRA observations of Saturn, we here search for further evidence of episodic satellite control of SKR and examine the time evolution, frequency dependence and phase of the 66-h modulation. Results will be compared with the phenomenology of the jovian control by Io.

The earlier reports of modulation by Dione presented data in intensity/time format at Dione's revolution period. We will use the method of power spectral analysis to cast the results in a more objective light, although composite intensity-time dynamic spectra will also be used to illustrate graphically the material. The power spectrum method used is that of Deeming⁵, and has been applied to the PRA data as described elsewhere².

Results

Figure 1 shows the results of power spectral analysis of SKR observed at 174 kHz between 28 October and 18 December

1980. This period of time brackets the Saturn encounter of 12-13 November. The spectrum spans the range of periods from just under 10 h to just above 100 h, corresponding to the range of expected periods of revolution of Saturn's five major innermost satellites and the planetary rotation itself. Aside from the dominant peak near 11 h, which corresponds to modulation of the SKR at Saturn's rotation period, no other statistically significant peaks are evident in the spectra, and, in particular,

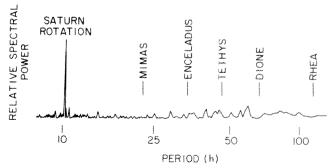

Fig. 1 The results of power spectral analysis of SKR observed at 174 kHz between 28 October and 18 December 1980. Only SKR events exceeding a flux density threshold of 2×10^{-21} W m⁻¹ (normalized to a standard observer-Saturn distance of 1 AU) were used to eliminate a severe inverse-R-squared bias during this period. The only statistically significant modulation occurs at the 10.66-h Saturn rotation period.

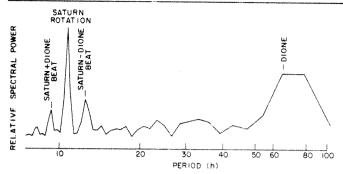

Fig. 2 Power spectral analysis like that described in Fig. 1 but for a shorter interval of time (10-18 November) at 59 kHz observing frequency. Statistically significant peaks occur at the Saturn rotation period, at 66 h, and at the two principal heterodynes between these periods.

there is no significant spectral power at any of the satellite periods. Several other radio frequencies in the SKR band, both above and below 174 kHz, show identical results.

The 66-h modulation

If we examine the PRA low frequencies for the time interval nearer encounter, significant modulation appears near a period of 66 h. To within the 10-h resolution limit inherent in the spectrum near the low-frequency end, this period corresponds to Dione's period of revolution of 65.68 h. In particular, Fig. 2 shows the power spectrum for the analysis interval 10-18 November at an observing frequency of 59 kHz. This 9-day period is equal to three Dione revolutions. The four principal peaks in the spectrum are Saturn's rotation period² (10.66 h). Dione (66 h), and the two principal heterodynes between the 10.66 and 66-h periods. A composite dynamic spectrum of the same time interval (Fig. 3a) shows the phase of this 66-h modulation. Here, it is clear that the predominant effect is an apparent quenching of the low-frequency SKR near 270° heliocentric phase, that is when Dione is above Saturn's dusk meridian. There is a pronounced gap in the emission occurrence levels at this phase, especially at frequencies below ~200 kHz. Above 200 kHz the emission has begun to fill into the gap, suggesting a frequency dependence of the effect. In addition, because this analysis interval spans the time of closest approach to Saturn, so that the emission is observed from two very different Sun-Saturn-spacecraft angles, the modulation would appear to be locked with respect to the Sun rather than the observer. Note also that there is an additional modulation apparent in Fig. 3. Peaks in the occurrence probability contours occur at 40°, 100°, 160°, 220°, and 340° Dione phase (filled triangles) and are due to the planetary-rotation modulation which is within 3% of an integral multiple of Dione's period. The phase of the expected, but missing, episodes of rotation-modulated SKR are also indicated (open triangle). During this 9-day

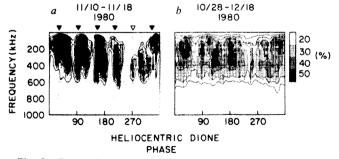

Fig. 3 Composite frequency-time dynamic spectra formed by stacking SKR events at Dione's heliocentric period of revolution for the time interval a 10–18 November 1980 and b 28 October-18 December. Grey-shaded contour intervals show the resultant per cent occurrence probability levels. The dynamic spectra cover the frequency range 1.2–1,000 kHz. ∇ in a show the phase of expected peaks in occurrence levels due to Saturn's rotation; \triangle shows the 'missing' events. Only events exceeding $2 \times 10^{-21} \, \mathrm{W \, m^{-2} \, Hz^{-1}}$ at 1 AU were used.

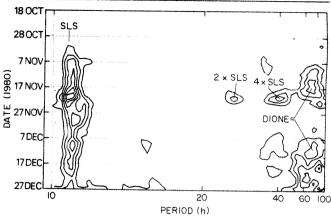

Fig. 4 Results of power spectral analysis on 12-day spans of data from 12 October to 31 December 1980. Spectra were stepped in 1-day increments. Observing frequency was 78 kHz. Contours show levels of relative spectral power as a function of spectral period and centre date of 12-day span. The contour intervals are 15, 25, 35, 45, 55 and 65% of the maximum spectral power. The modulation at Saturn's rotation period (indicated here as SLS, or Saturn longitude system) and two and four times the period are indicated. The broad spectral peak near Dione's period of revolution can be seen to occur in two episodes.

period, three such episodes fail to occur. It is this gap which produces the peak in the power spectrum at 66 h in Fig. 2.

Figure 3b supports the long-term power spectral result of Fig. 1. It shows again that when data are examined over extended periods, in this case 28 October to 18 December including the 9-day interval in Fig. 3a, the emission occurrence probability levels are distributed randomly in Dione phase. Modulating effects near Dione's period disappear over the long term.

Satellite modulation survey

Before exploring the 66-h modulation further, it is useful to investigate the possibility of additional episodic, short-term modulations. To do this we computed power spectra over 12-day intervals between 12 October and 31 December 1980. Successive spectra were stepped along in 1-day increments, thus yielding an independent spectral estimate on every twelfth point. Each spectrum covered the 90-h window in period spacing from 10 to 100 h (as in Fig. 1). The result is shown in Fig. 4. Contour intervals are proportional to spectral power. The dominant feature is, as might be expected, the Saturn rotation modulation at 10.66 h. It is statistically dominant over almost the entire analysis interval. Outside of this modulation, no significant power appears at periods ≤50 h, except for subharmonic power at 2 and 4 times 10.66 h which appear for a short interval of time over the computation window centred on 21 November 1980 when the modulation at the fundamental is strongest. Above 50 h significant modulation appears twice briefly near 66 h. A third island of significant spectral power slightly below 66 h is centred on 22 December; however, closer examination of the data shows it to be due to an accidental

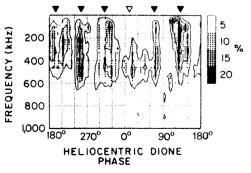

Fig. 5 As in Fig. 3 but for the period 2-14 December 1980. Only events exceeding a flux threshold of $8\times10^{-21}\,\mathrm{W}\,\mathrm{m}^{-2}\,\mathrm{Hz}^{-1}$ (at 1 AU) were used. The 'Dione gap' has shifted to about 30° phase. Note that the abscissa is shifted 180° for clarity.

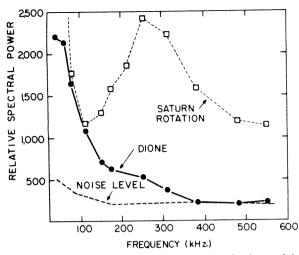

Fig. 6 The decline with increasing frequency in effective modulation at Dione's period of revolution. Spectral power at Dione's period falls to the spectrum noise level at 385 kHz. Modulation due to Saturn's rotation remains strong over the entire band. Analysis interval from 10–18 November 1981. Only events exceeding 2×10^{-21} W m⁻² Hz⁻¹ at 1 AU were included.

reoccurrence of data gaps at this period. At still longer spectral periods additional minor peaks appear; however, their significance is in doubt because they are so near the lowfrequency limit of the power spectrum. Identical surveys at several other radio frequencies in the SKR band have yielded identical results. Thus no evidence of short-term modulations of the SKR by any other satellites exists, at least during the late October to December period.

The two significant peaks in Fig. 4 labelled Dione correspond, first, to an interval of time around encounter, mentioned in the discussion of Figs 2 and 3, and, second, to an interval of time in early December. The activity for the period 2-14 December is shown in Fig. 5 in composite frequency-time dynamic spectrum format. The occurrence probability levels are again shown using gray-shaded contour intervals, and the data are organized in heliocentric Dione phase. The expected Dione phase of modulations due to planetary rotation are shown at 10.66-h intervals. The open triangle indicates the 'missing' rotation, in this case 5 missing rotations over the 13-day interval covered. Instead of occurring near 270° Dione phase as was the case near encounter (Fig. 3), the emission gap is now centred on about 30° Dione phase (note shifted phase scale for clarity). The gap is much more pronounced at the lowest frequencies, below 200 kHz, and has disappeared at 400 kHz and higher. This same frequency behaviour was noted with regard to the 66-h modulation observed near encounter.

Frequency dependence

Using power spectra computed at several observing frequencies, we have examined the dependence of the Dione modulation on frequency throughout most of the SKR frequency band. Both Figs 3 and 5 suggested a frequency dependence may exist. The analysis interval extends over the 9-day encounter period shown in Fig. 3 and the results are shown in Fig. 6. Here the power at 66 h is compared with the 10.66-h modulation of the SKR due to Saturn's rotation. The noise level inherent in the power spectra at each frequency is also shown. Note that the magnitude of the 66-h modulation falls by almost a factor of four between 40 and 200 kHz, and reaches statistically insignificant levels at frequencies exceeding ~385 kHz. In total this represents an order of magnitude drop in spectral power over a decade in frequency, f, thus corresponding to a 1/f decline. By comparison, the planetary rotation modulation is strong

Received 13 May; accepted 7 July 1981.

throughout the frequency band, although it also varies with frequency. The rotation modulation approximately follows the shape of the emission flux density spectrum which also has a peak near 200-300 kHz (ref. 6). Below 100 kHz, however, the Saturn rotation modulation increases sharply due, we think, to a possible low-frequency (f < 100 kHz) emission component⁴

Only those radio events which exceeded a constant flux density threshold, in this case $2 \times 10^{-21} \,\mathrm{W m^{-2} \, Hz^{-1}}$ normalized to an equivalent observer-Saturn distance of 1 AU, were used to derive the frequency dependence shown in Fig. 6. Because there is some dependence of spectral power on the choice of flux threshold used, we examined the effect on the frequencydependence curve of varying this threshold. We found that, over a two decade range of flux densities, the modulation is always greatest at low frequencies with no statistically significant modulation appearing at f > 400 kHz. The results shown for early December (Fig. 5) are clearly consistent with this frequency dependence. We conclude that the 66-h modulation is strongly and inversely dependent on frequency.

Discussion

In the two intervals of time during which significant modulation occurs near a spectral period of 66 h the modulation (1) varies inversely with frequency and (2) persists for short intervals limited to 3-5 cycles of the 66-h period. The phase of the modulation is not constant, however. The observed phase of the emission gap changes from about 270° Dione phase for the November episode to ~30° phase for the December episode.

Phenomenologically this modulation differs dramatically from the way in which Io is observed to control the jovian emission (DAM). Io enhances rather than quenches the emission level of DAM; the Io effect is, to first order, independent of frequency; the phase of the emission is fixed with respect to the observer, not the Sun; and, finally, Io control is not an intermittent phenomenon.

If Dione is responsible for the 66-h modulation of the SKR, it is difficult to imagine what mechanism could cause such an effect. Certain features, namely the cutoff in observed emission level and the 1/f frequency dependence, are consistent with preferential absorption or strong refraction of SKR at low frequencies due to a moderately dense plasma associated with Dione. In fact, Pioneer 11 (ref. 7) and Voyager^{3,8} observations seem to support the existence of a 15 to 20 cm⁻³ electron plasma in the vicinity of 4-8 R_s . Dione, at 6.3 R_s , is within this plasma. However, other observed features of the modulation are inconsistent with this simple picture. One might expect, for example, a more pronounced modulation on the inbound observing period when Voyager, at a saturnigraphic latitude of +8°, viewed the emission from a point closer to the equator plane. Instead, the outbound geometry seems more favourable, when Voyager was at +26° latitude. Also, during the first episode of the Dione modulations, one of the SKR gaps occurred near closest approach when Voyager 1 was at high southern latitudes. Furthermore, the variable phase of the modulation makes any simple absorption picture difficult to model.

An alternative method of cutting off the emission includes a more dynamic interaction between Dione and the radio source region. There is some evidence that Dione may be stimulating field-aligned currents, perhaps as Io does at Jupiter. If so, Dione may act, in some as yet unspecified way, to quench the emission process physically. The Dione flux tubes do intersect the modelled⁶ radio source region; however, the orbital phase of the intersection is near 120° Dione phase, not the preferred 270° or 30° gap locations. Thus neither the absorption nor dynamic quenching models are especially attractive, and we hope that the Voyager 2 observations of SKR near closest approach will shed some light on this perplexing problem.

Control of Saturn's kilometric radiation by Dione

W. S. Kurth*, D. A. Gurnett*, & F. L. Scarf*

*Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA †TRW Defense and Space Systems, One Space Park, Redondo Beach, California 90278, USA

Voyager 1 observations of Saturn's kilometric radio emissions reveal a strong but apparently transitory control by the orbital phase angle of Dione. This may be a geometrical effect and a time-variable plasma torus associated with Dione could explain most of the observed details of the Dione modulation by creating a shadow zone near the equatorial plane.

THE Voyager planetary radio astronomy investigation provided the first incontrovertible evidence of nonthermal radio emissions from Saturn¹. The radiation spectrum peaks in the kilometre wavelength regime near 200 kHz and periodicities in the occurrence of the radio bursts give an internal planetary rotation period of 10 h, 39.9 min (ref. 2). Observations of the radio emission at 56.2 kHz by the plasma wave instrument on Voyager 1 revealed a modulation of the intensity of the radio emission with a period very close to the orbital period of Dione indicating that some control of the emission was a function of the orbital phase of the moon³. This control was also reported by the planetary radio astronomy investigation4 with the maximum effect seen at lower frequencies⁵, but extending as high as 385 kHz. The magnitude of the Dione influence is not constant in time and was strongest near closest approach. (Dione has a radius of 560 km (ref. 6) and is 6.29 Rs from Saturn in an orbit whose eccentricity is 0.002.)

Here we analyse the effect of Dione's orbital phase on the emission of radio waves from Saturn to explain the apparent transitory nature and suggest a mechanism for the interaction with the moon.

Nature of Dione's influence

We begin by describing the saturnian kilometric radio (SKR) spectrum below $\sim\!56\,\mathrm{kHz}.$ Figure 1 is a typical event as seen by the plasma wave instrument as Voyager approached Saturn on 11 November 1980. The amplitude of radio signals as a function of time for the upper five channels of the plasma wave spectrum analyser are shown. The height of the solid black area represents the average power flux (W m $^{-2}$ Hz $^{-1}$).

The radio burst shown in Fig. 1 increases in amplitude with increasing frequency to a peak at least as high as the upper frequency limit of the instrument (56.2 kHz). The emission is highly time-variable, changing in amplitude by nearly an order of magnitude on time scales of a few minutes. While gross amplitude changes track fairly well from one channel to the next, many of the fine-scale features are totally uncorrelated with those of adjacent channels indicating narrowband elements in

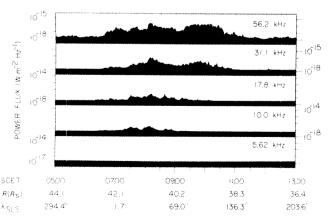

Fig. 1 A typical example of saturnian kilometric radiation extending from near 10 kHz to above 56 kHz.

the spectrum. Hence, the temporal variations of the SKR are similar in many respects to the auroral kilometric radiation from the Earth. The low-frequency cutoff of the saturnian emission has been reported to be frequently near 60 kHz; however, Fig. 1 shows that the emission is detectable at frequencies as low as 10 kHz.

We specifically consider the correlation between the orbital phase angle of Dione, ϕ_{Dione} , and the amplitude of the kilometric radio emission which was originally demonstrated by Gurnett *et al.*³, who showed that in addition to the 10 h 39.9 min modulation related to Saturn's rotation, the emission was strongest when Dione was in the local dawn sector. Figure 2 plots the hourly average power flux of the radio emission at 56.2 kHz as a function of radial distance; also shown is a dashed line

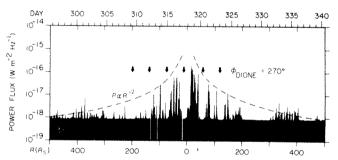

Fig. 2 A plot of hourly average values of the 56.2 kHz plasma wave receiver channel as a function of radial distance from Saturn. The narrow bursts are emitted at a period of $\sim 10 \text{ h}$ 39.9 min and generally rise in amplitude with decreasing R approximately as R^{-2} . The arrows indicate times when Dione is at local dusk and correspond closely to periods when there is little or no radio emission.

with a R^{-2} dependence. The arrows indicate times when Dione was at local dusk ($\phi_{Dione} = 270^{\circ}$) and correspond to periods when there is little or no kilometric emission. Figure 2 suggests that the effect of Dione is to suppress or attenuate the saturnian radio emission when $\phi_{\text{Dione}} = 270^{\circ}$. (The nearly-constant minimum signal strength of $\sim 8 \times 10^{-19} \text{ W m}^{-2} \text{ Hz}^{-1}$ corresponds to the receiver noise level.) The peaks of the 10 h 39.9 min bursts approximately follow a R^{-2} dependence except for periods within $\sim 200 R_s$ when the amplitude of the peaks fall well below the curve coincident with the passage of Dione through the dusk sector. Beyond $\sim 200 R_s$ on the inbound leg and $\sim 165 R_{\rm s}$ on the outbound leg the periodic suppression in phase with Dione's orbital motion is no longer evident. The Dione suppression might explain the apparent north-south asymmetry in the source strength at lower frequencies reported by Warwick et al.4 since Dione was near local dusk for most of Voyager 1's trajectory through southern latitudes.

Analysis of traces similar to that in Fig. 7 of ref. 3, and the present Fig. 2, shows that a clear signature of the Dione modulation is not present before day 308 or after day 325 of 1980. These dates correspond to Voyager-Saturn distances of 227 and $165 R_s$, respectively. To illustrate the transitory nature of the Dione effect further, we show the result of a statistical study of the occurrence of kilometric radiation as a function of Dione's

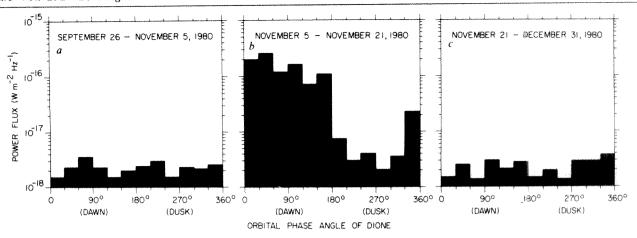

Fig. 3 Plots of the 98% amplitude as a function of Dione's orbital phase angle for the distant inbound, near encounter, and distant outbound Voyager 1 trajectories at 56.2 kHz. Note the strong Dione control near encounter and the complete lack thereof during the distant inbound and outbound passes.

orbital phase angle. The bar graphs in Fig. 3 show the power flux below which 98% of the samples fell for each of 12 phase angle bins. Recall that phase angle is measured positive eastward from a plane containing Saturn's rotation axis and the Sun, with 0° at local midnight. Figure 3b includes all data covered by Gurnett et al.³ when the Dione effect is qualitatively most apparent. Figure 3a, c present results from the inbound and outbound legs when little or no Dione control was apparent. It is clear the distant inbound and outbound data show no significant trend. On the other hand, the difference in amplitude at the 98% level between phase angles near 90° and 270° is about two orders of magnitude for the two-week period near closest approach. For this period, Dione clearly has an important role in determining the amplitude of Saturn radio emissions at 56.2 kHz.

Discussion

There are many possible interactions by which a moon may influence the generation of magnetospheric radio emissions. We shall attempt to narrow the list of likely candidates to one or two which are consistent with all or most of the observations. We assume the SKR originates at relatively low altitudes on high latitude field lines, presumably in the auroral region as suggested by Kaiser et al.⁸.

We first need to explain the transitory nature of the effect. A truly transient process which is active for two weeks and then inactive for long periods of time requires a mechanism to stimulate the control. The long-term studies show no Dione effect⁴ so the active periods must be quite rare. Hence, it is strange that the effect was seen coincidentally with closest approach and we shall argue that the effect is not transitory but depends on the location of the observer.

The simplest explanation of the transitory nature of the Dione control is geometric in nature and specifically related to Voyager's low latitude or small distance from the equatorial plane of Saturn around closest approach. The effect became apparent around day 308 when Voyager 1 was at 8.3° latitude and about $33~R_{\rm S}$ above the equatorial plane. On day 325, when the effect apparently disappeared, the spacecraft was at a latitude of 25.4° and $71~R_{\rm S}$ above the equatorial plane. A second episode of Dione control in early December has been reported by the planetary radio astronomy team⁵. The effect is visible in the plasma wave data at $56.2~{\rm kHz}$, however, we are not confident in interpreting our data as a genuine Dione effect at this time. Should this be a valid episode, however, our conclusion of a geometric effect would be in jeopardy.

Figure 2 showed Dione attenuated the saturnian radio emission as opposed to stimulating or amplifying it. The attenuation could be caused by a propagation effect or by a basic change in the source itself. In either case, the most likely interaction mechanism is a change in magnetospheric density associated with the satellite. A decrease in density could only be accomplished by a sweep-up effect and this is hardly a time-variable process capable of disturbing the inner magnetosphere on time

scales of a few days. An increase in magnetospheric density, however, is plausible as the result of a process which liberates particles from the moon making the moon a plasma source. This type of process occurs in the jovian system with Io being the primary source of plasma.

Frank et al.9 argued that Dione could be a reasonable source for an oxygen torus at Saturn. A peak in the ion density at Dione's orbit with density and temperature profiles reminiscent of those at Io in Jupiter's magnetosphere suggests that Dione, like Io, is a plasma source. Also, the water ice or frost surface of Dione opens the possibility of plasma production through dissociation and ionization. A ledge-like structure in the plasma torus near Dione's L-shell has been reported10, and similarities of this structure with that observed at Io in Jupiter's magnetosphere suggest a plasma source. Evidence from the Pioneer 11 magnetometer¹¹ also suggests a process involving plasma production. On the inbound Pioneer trajectory, significant magnetic field perturbation was seen at Dione's L-shell but no effect was observed on the outbound leg. Local time of Dione was $\sim 21 \text{ h} \ (\phi_{\text{Dione}} \sim 315^{\circ})$ and $\sim 1 \text{ h} \ (\phi_{\text{Dione}} \sim 15^{\circ})$ for the Pioneer inbound and outbound Dione L-shell crossing, respectively. Although there are several possible explanations, this magnetic field signature is consistent with a ring current associated with Dione which varies with ϕ_{Dione}

An increase in magnetospheric density could affect radio emissions by modifying conditions at the source of the radiation. There is some evidence that the Earth's auroral kilometric radiation is quenched by increasing the density in the source region $^{12-14}$, however, Gurnett and Anderson have stated that this is not very likely. Another difficulty with direct modification of the source is that the plasma produced at Dione would have to have easy access to the source. If the radio source were in the auroral region, it is unlikely that an equatorial plasma source at $L \sim 6$ could effectively modify the density in the auroral zone.

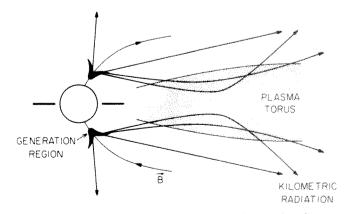

Fig. 4 How a Dione-related torus would refract radio waves from Saturn away from the equatorial region. A similar effect was found for broadband kilometric radiation from Jupiter.

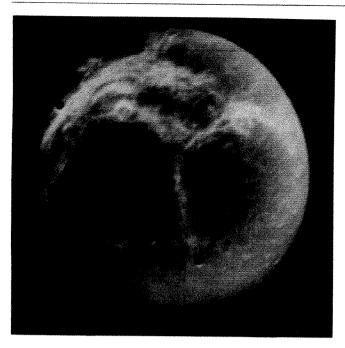

Fig. 5 An image of the trailing hemisphere of Dione taken by Voyager 1 when Dione was near local dusk. Note that this sunlit hemisphere is dominated by bright wispy features which are probably fresh outcroppings of water ice or frost. The frost may be a source of plasma for a torus whose density fluctuates with the same period as Dione's orbit.

The alternative is to assume that an increase in plasma density associated with Dione affects the propagation of radio waves through refraction or reflection as represented in Fig. 4. We used the model torus from ref. 3, although the model shown by Bridge et al.10 would give essentially the same effect. Waves with frequency less than or equal to the local plasma frequency in the torus cannot penetrate the torus. Waves of higher frequency will be refracted away from the equatorial region, although the effect will diminish with increasing frequency.

Many observations suggest that the model shown in Fig. 4 is viable. First, the density of the plasma torus as measured by Pioneer 11 (ref. 9) and Voyager 1 (refs 3, 10) is of the order of 40 cm⁻³ corresponding to a plasma frequency of 57 kHz. Waves below this frequency could not penetrate the torus and waves well above 100 kHz could undergo substantial refraction. This refraction is consistent with the frequency dependence of the Dione effect reported by Desch and Kaiser⁵, as lower frequencies tend to be refracted most. Second, because preliminary observations 3,10 suggest the plasma is confined near the equator, waves propagating near low latitudes would be most affected. Therefore, we expect a low-latitude shadow zone as was found for the jovian kilometric radiation 16,17. A shadow zone near the equator would explain the presence of a Dione control only near encounter when Voyager 1 was close to the equator. The asymmetry in the latitude at which the effect appears and disappears could well be a local time asymmetry in the thickness or density of the torus.

How then does the orbital phase angle of Dione modulate the emission? It is important first to establish that the modulating effect of the torus is longitudinally symmetric. The evidence is embodied in Fig. 7 of ref. 3 and Fig. 2 of this paper. Note that the phase of the Dione effect did not change as Voyager moved from near local noon before encounter to local early morning after the encounter. If there were a localized cloud of plasma which orbited Saturn, a phase shift would have been apparent as the viewing point changed. As the phase did not change, the modulation effect must be longitudinally symmetric. This longitudinal symmetry should be fairly easily achieved due to the rapid corotation of the plasma which will quickly distribute plasma in longitude even though the source may be localized.

To explain the dependence of the torus density on the orbital phase angle of Dione, we suggest that Dione may be a plasma

source only when it is near local dusk. Hence, the plasma cloud produced dissipates on a time scale of about a day so that by the time Dione is near local dawn the torus density has decreased by a factor of say, two. Because the trailing hemisphere of Dione is always the same, a hemispheric asymmetry in direct particle sputtering processes cannot explain the dawn-dusk asymmetry. On the other hand, there are obvious asymmetries in the surface features of Dione. Figure 5 shows Dione near local dusk. The trailing hemisphere shows a complex pattern of wispy features which do not appear on the opposite hemisphere of Dione. Smith et al.6 suggest the bright markings are controlled by a regional system of fractures or faults possibly formed or reopened by internally generated stresses. The bright material is probably water ice and it is tempting to speculate that this relatively fresh surface frost is photosputtered when the trailing hemisphere is sunlit as it is when Dione is near local dusk, or that photodissociated volatiles produce the plasma.

Carlson¹⁸ and Frank et al. 9 have discussed the rings as possible sources of plasma in the saturnian magnetosphere. Of processes such as photosputtering, ion sputtering, sublimation with subsequent photodissociation, and others, photosputtering seems to be the most efficient mechanism. It would be a convenient mechanism for an orbital phase-dependent source of plasma at Dione in view of the hemispherical asymmetry of the wispy features shown in Fig. 5. Taking the hydrogen atom flux derived by Carlson¹⁸ of $\sim 10^8 \text{ cm}^{-2} \text{ s}^{-1}$, Dione can produce $\sim 10^{24}$ atoms s⁻¹ (assuming the entire sunlit hemisphere is a source and photosputtering is applicable to Dione). If the time scales for both creation and dissipation of the plasma torus are ~ 1 day (to provide a 2.74-day modulation period), then the production/loss rate must be the order of $10^{28} \, \mathrm{s}^{-1}$. We have assumed a torus 4 Rs thick, centred at 6 Rs, which fluctuates between 20 and 40 cm⁻³. Obviously, photosputtering is not sufficient to produce a dense torus on the time scale of a day.

If we assume that the other processes considered by Carlson are no more efficient than photosputtering, we must consider a mechanism which is based on the release of volatiles from fractures in Dione's crust and subsequent photodissociation. Presumably the volatiles would be released into the exosphere at a constant rate but preferentially from the wispy hemisphere. Photodissociation of the molecules would occur only during the dusk sector of Dione's orbit when the wisps are sunlit. This mechanism is largely speculative and production rates depend on rate of volatile release, the type of volatile, and photodissociation rate. However, the injection rate at Io has been estimated 19 at $2 \times 10^{29\pm1}$ ions s⁻¹, about 200 times that required at Dione.

The proposed fluctuating torus model also requires a dissipation rate of the order of 10^{28} s⁻¹. Richardson et al. 19 point out that outward radial diffusion through flux-tube interchange is the predominant loss mechanism at Jupiter and given that oxygen or some other heavy ion is an important constituent of the Dione torus^{9,10} the centrifugally-driven interchange instability is likely to be important at Saturn, also.

We have arrived at a model which is similar in part to effects observed at Jupiter. We propose that Dione is responsible for the production of plasma when it is near local dusk which forms a longitudinally symmetric torus. The torus then casts a radio shadow on low latitudes so that the saturnian radio emission cannot be seen by a spacecraft near the equator. The torus decays with a time constant of about one day so that as Dione approaches local dawn the usual saturnian emission reappears. The possibility of an additional Dione-control episode⁵ in early December, 1980 at $\phi_{\text{Dione}} \sim 40^{\circ}$, however, presents an even more perplexing situation to be explained involving a shift in the phase of the control.

Pre-encounter distributions of Saturn's low frequency radio emission

T. D. Carr*, J. J. Schauble[†] & C. C. Schauble[†]

- * Department of Astronomy, University of Florida, Gainesville, Florida 32611, USA
- † University of Florida Graduate Center, Eglin Air Force Base, Florida 32542, USA

An analysis of Voyager 1 pre-encounter data is presented in which one-month averages of flux density from Saturn are determined as functions of both central meridian longitude and frequency. Comparisons of corresponding distributions for two one-month intervals seven months apart yield information on their stability, and a redetermination of the magnetospheric rotation period.

THE detection of a nonthermal component of Saturn's thermal radio emission has proved to be difficult. No synchrotron radiation from the planet has yet been found, and pre-Voyager searches for a nonthermal component at low frequencies were inconclusive. An unsubstantiated identification of such emission1 was made near 1 MHz, but not until Voyager 1 had approached to within 3 AU was a nonthermal radio component positively identified2. This radiation is not unlike the kilometric bursts from the terrestrial and jovian magnetospheres. Most of the activity is between ~70 and 300 kHz, and is polarized predominantly in the right hand sense²⁻⁴. The probability of occurrence tends to vary in a more or less repeatable way with

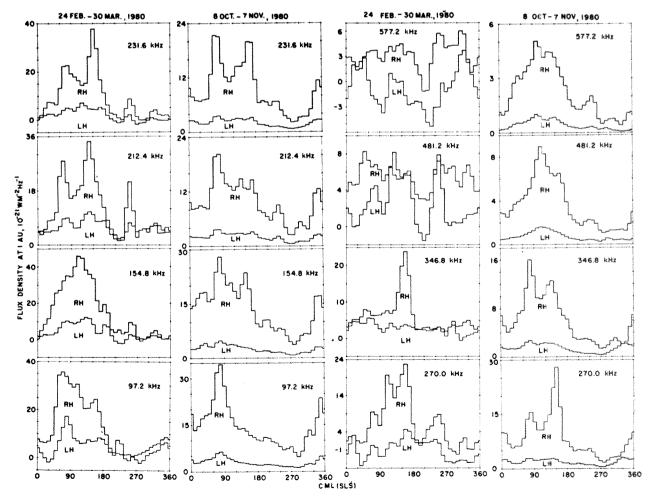

Fig. 1 Histograms of average flux density per 10° interval as a function of central meridian longitude for specified time intervals and frequencies. Averaging extends over inactive as well as active periods. Right hand (RH) and left hand (LH) polarized components are plotted separately. Small and negative flux densities result from background fluctuations when Saturn radiation is very weak, accentuated at times by slight errors in baseline determination

the rotation of the planet. From an analysis of this periodicity over several months before the Voyager 1 encounter, Desch and Kaiser³ arrived at a rotation period of 10 h 39 min $24(\pm 7)$ s, the presently accepted value for Saturn's magnetosphere. This period is the basis for the Saturn longitude system (designated SLS) in current use for specifying central meridian longitude (CML).

Observations

The data used in this analysis were obtained by Voyager 1 during two periods extending from 24 February to 30 March 1980, and from 8 October to 7 November 1980. Closest approach to Saturn was on 12 November 1980. The measurements were made with the low band receiver of the planetary radio astronomy experiment⁵, at 28 selected frequencies from 20.4 to 1,038 kHz. In calculating flux density as functions of CL and frequency, the averaging intervals covered inactive as well as active periods. Data reading and manipulation was computerized, except for preliminary editing when data containing interference from within the spacecraft, from the Sun, or from Jupiter were excluded. Solar bursts were easily identified but Jupiter bursts, which more closely resemble those from Saturn, were identified in most cases by locating the same event on the Voyager 2 record and noting the difference of onset times. As Voyager 2 was much closer to Jupiter than Voyager 1, nearly every jovian event appearing on a Voyager 1 record could also be seen on the corresponding Voyager 2 record with greater intensity and earlier onset time. For each of the two circularly polarized components at each frequency one or more short segments of undisturbed baseline were selected from each 24-h run (except for a very few runs in which no activity lull occurred). Zero-flux density baselines fitted to these segments were subtracted from the data points within that 24-h interval. Following the background subtraction and the application of an appropriate calibration factor, flux densities were normalized to a standard 1 AU spacecraft distance. Histograms of average flux density for 10° CML intervals formed the basis for subsequent analyses.

Results and discussion

Eight pairs of representative histograms are shown in Fig. 1. The two in each pair are for the same frequency, one for the first and the other for the second data period. Although the CML regions of maximum and minimum activity approximately coincide for histograms at the same frequency, the differences seen are probably due to statistical fluctuations. An extreme case of this is seen in the 481.2 and 577.2 kHz histograms, in which the radiation during the first data period is so weak that background fluctuations dominate. At the same two frequencies for the second data period, when the spacecraft was close to the planet, the distribution is very clearly defined.

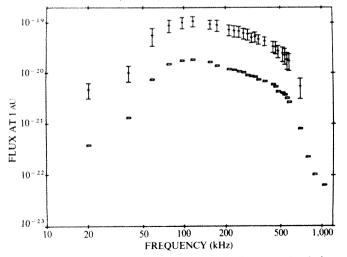

Fig. 2 Special distributions of average flux density (lower curve) and of 'peak' or 97 percentile flux density (upper curve). Error bars indicate 90% confidence range for the latter. Flux densities in Wm⁻² Hz⁻¹.

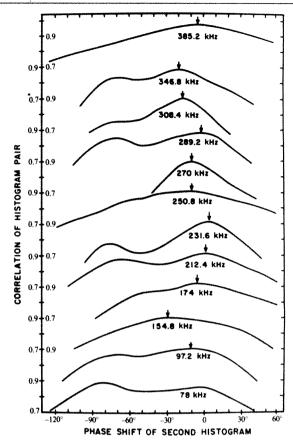

Fig. 3 Cross correlation of pairs of single-frequency histograms as a function of the longitude shift of the second histogram in the pair. Curve maxima are indicated by arrows.

In addition to statistical fluctuations, there seem to be systematic differences. For example, a secondary peak often appears near 360° in the second histogram which is not present in the first one. Such differences are unlikely to be latitude effects. The saturnigraphic latitude of the spacecraft on the median dates of the two data periods was 9.1° and 8.7°, respectively, unlikely to cause an observable effect: nor was the difference in saturnian local time at the spacecraft enough. The systematic differences are most likely due to temporal instability possibly caused by some alteration of the magnetospheric plasma distribution, and even of the multipole structure of the magnetic field, over the seven-month interval between the two data sets.

Figure 1 shows that the right hand (RH) circularly polarized component is much stronger than the left hand (LH) one. The histograms suggest that the ratio of LH to RH flux densities may be smaller in the vicinity of the main peak (near 100°) than elsewhere; however, this ratio would be subject to large errors

outside the main peak region because of the relatively low flux density values there.

The spectral distribution of average flux density (RH and LH combined), shown in Fig. 2, was obtained by integrating the histograms of average flux density against CML for each of the 28 frequencies for the second data set. This curve closely agrees with that corresponding to the first data set, except at those frequencies at which the signal-to-noise ratio in the first set was poor. Nearly all of the radiation occurs below 1 MHz, and the broad spectral peak has its maximum at ~150 kHz. Figure 2 also shows the spectral distribution of the 97-percentile level of the individual flux density measurements (RH and LH combined) in the second data set. This is the level which is exceeded 3% of the time. Each point on the 97-percentile curve is the mean of the 24-h 97-percentile values for the 1-month period.

Integration of the average curve of Fig. 2 yields the 1 AU equivalent of the average power per unit area (5.3× 10⁻¹⁵ Wm⁻²) reaching the spacecraft at all frequencies. The corresponding isotropic equivalent average power of the saturnian radio source is 1.5×10^9 W. This is $\sim 0.4\%$ of the isotropic power equivalent for all the jovian emission below 40 MHz, or about five times that of the jovian kilometric emission (below 300 kHz)⁶. A similar integration of the 97-percentile curve in Fig. 2 could not be used to calculate a 97-percentile isotropic equivalent power, because emission peaks do not occur simultaneously at all frequencies.

Single-frequency pairs of histograms such as those in Fig. 1 allow a more precise determination of Saturn's magnetospheric rotation period. Our method was previously used successfully to redetermine Jupiter's radio rotation period⁷. Each histogram in a single-frequency pair represents data from a period of about a month, and the interval between the medium dates of the two data periods was \sim 224 days (1.935 \times 10⁷ s). The histograms are based on the SLS rotation period3. From the measured shift of the second histogram in each pair with respect to the first, the correction to be applied to the SLS period was calculated. The histogram for the RH component was used in each case although the sum of the RH and LH components could have been used instead. The correct histogram shift was indicated by the principal maximum of the cross correlation function for the pair. The corrected rotation period, P_{new} , was then calculated from the formula

$$P_{\text{new}} = P_{\text{SLS}} \left(1 + \frac{P_{\text{SLS}} \Delta L}{360T} \right)$$

where P_{SLS} is the SLS period, ΔL is the longitude shift (in degrees) of the second histogram with respect to the first at the cross correlation maximum, and T is the time between the

median dates of the two data sets from which the histograms were plotted. The signal-to-noise ratio during the first data period was considered adequate for cross-correlation of 12 of the 28 originally selected frequencies. Plots of the regions about the principal peaks of the cross-correlation functions for the histogram pairs at these 12 frequencies are shown in Fig. 3. The principal peaks in 11 curves occur between -30° and 4°. Most of the curves also exhibit a secondary peak in the vicinity of -80°. For 78 kHz the positions of the principal and secondary peaks are interchanged; this curve was rejected. The longitude shifts at the cross-correlation maxima for the 11 remaining curves, and the correlation coefficients are presented in Table 1. These 11 measurements are not completely independent, because whenever activity is observed on a given frequency channel, it most likely occurs at about the same time on one or more nearby channels. Desch and Kaiser (personal communication) have found the 1/e decorrelation bandwidth of the Voyager preencounter Saturn emission to be ~115 kHz. We therefore averaged our 11 shift measurements in three groups, the centre frequencies of which are separated by nearly this amount, as indicated in Table 1. The resulting averages, which lie within -1 s of the mean (10 h 39 min 22 s), are believed to be largely independent. The mean differs from the SLS period by only 2 s The close agreement of our three measurements suggests that their statistical precision is better than the ± 7 s quoted for the SLS determination. However, Desch and Kaiser believe that this uncertainty is due to a basic instability in the averaged pre-encounter saturnian emission pattern. If this is true it suggests that the close agreement of our measurements is accidental. Further rotation period determinations over different time intervals should settle this question.

To approach maximum statistical precision using our method, a near-optimum combination should be sought for three intervals: (1) the data collection interval for the first histogram; (2) that for the second histogram (assumed to be as close to encounter as possible without producing excessive latitude change), and (3) the interval between the median dates of the two histograms. The latter should provide an adequate temporal baseline over which to measure the notation period, yet not make the Saturn events in the first interval too weak or too infrequent. We believe that a large part of the difference in the shapes of our first and second histograms in each pair results from the relatively low signal intensity relative to the background noise during the first interval. We should be able to improve our precision (and evaluate it) soon by using more recent Voyager 1 and 2 data.

We thank M. D. Desch and M. L. Kaiser for unpublished decorrelation bandwidth data, and for helpful comments.

Plasma wave turbulence at planetary bow shocks

F. L. Scarf*, D. A. Gurnett & W. S. Kurth

* Space Science Department, TRW Defense and Space Systems Group, Redondo Beach, California 90278, USA † Department of Physics and Astronomy, University of Iowa, Iowa City, Iowa 52242, USA

Voyager 1 observations of plasma wave turbulence at Saturn's bow shock are discussed and compared with corresponding data from Jupiter, Earth, and Venus. The results suggest that the plasma instabilities that develop at the lower Mach number bow shocks of the terrestrial planets differ from those found at the high Mach number bow shocks of the outer planets.

As the solar wind streams out from the Sun, its flow speed remains constant, but its plasma density, ion and electron temperatures, and mean interplanetary magnetic field strengths all have distinct and varying radial profiles. Thus, the dimensionless interplanetary parameters that determine how microscopic plasma processes develop change with heliocentric distance. We therefore expect to find significant radial variations in several important interplanetary plasma phenomena. This is

very important to collisionless shock studies, in particular, because some combinations of plasma parameters occurring naturally in the solar wind have not yet been attained experimentally.

The planetary bow shock also forms in the solar wind, and this means that the characteristics of these very high Mach number discontinuities will vary across the Solar System as the expanding wind encounters each planet at a different radial position. As the processes that develop at the bow shock directly affect the properties of the post-shock plasma that actually impacts the ionopause or magnetopause, comparative planetary studies must include comparison of the bow shock turbulence spectra and associated wave-particle interaction phenomena. We now discuss recent Voyager 1 observations of plasma wave turbulence at Saturn's bow shock, and present an initial comparison of these wave measurements with corresponding data from Jupiter, Earth and Venus. The results suggest that the plasma instabilities that develop at the lower Mach number bow shocks of the terrestrial planets differ from those found at the high Mach number bow shocks of the outer planets. Thus the state of the post-shock plasma varies significantly from one planet to another.

Saturn bow shock crossings

As noted by Gurnett et al.¹, the solar wind upstream from Saturn was remarkably quiet in the 10 Hz-56 kHz range covered by the Voyager 1 plasma wave instrument. The only regular signals observed in this region were repetitive series of Saturn radio emissions^{1,2}. We also detected a single cluster of intense 3 kHz noise bursts between 17.05 and 17.20 on 11 November 1980, when the Voyager to Saturn distance was 32.4 R_s. We interpret these 3-kHz waves as electron plasma oscillations associated with suprathermal electrons streaming back from the shock, but when these emissions disappeared, Voyager was still in the solar wind. Terrestrial experience with similar sequences of observations suggests that the bow shock was actually near the

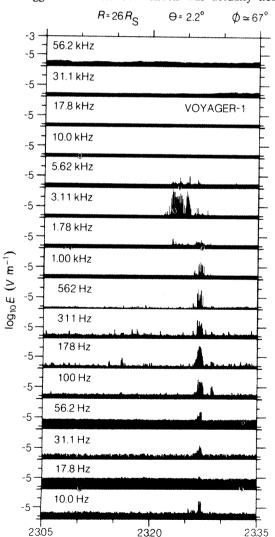

Fig. 1 Sixteen-channel measurements of plasma wave amplitudes at the inbound crossing of Saturn's bow shock. Several sporadic interference effects have been deleted. The 31.1-kHz and 56.2-kHz levels represent radio emissions from Saturn, and we interpret the 3.1-kHz waves as electron plasma oscillations.

spacecraft just after 17.00, but that the shock surface receded back towards the planet in response to a change in solar wind conditions. Similar 3-kHz bursts were detected again after 23.22, and these waves persisted until 23.27 when Voyager made its only inbound bow shock crossing at a radial distance of 26.1 $R_{\rm S}$. Figure 1 shows all of the 16-channel wave measurements for this event, and it can be seen that the shock was thin and well-defined in terms of the low frequency ($f \le 1$ kHz) wave activity. These bandpass channel amplitude profiles are very similar to those found when Voyager 1 approached Jupiter^{3.4}, and in both cases, the post-shock magnetosheath noise levels seem to be exceptionally low.

Just before 12.27, the wind speed (V) and density (N) were 420 km s⁻¹ and 0.11 ions cm⁻³, and the magnetic field strength (B) was about 0.3 nT. Here, the upstream proton and electron temperatures were $\sim 1.5 \times 10^4$ K and 2.3×10^4 K, respectively (J. Scudder, personal communication). For these parameters, the Alfvén speed, $V_A (= [B^2/4\pi N m_+]^{1/2})$, is only 20 km s⁻¹, and the magnetosonic wave speed, $V_{\rm ms} (= [V_A^2 + V_s^2]^{1/2})$, with $V_s = [(5kT_+/3 + kT_-)/m_+]^{1/2})$, is ~ 28 km s⁻¹. Hence, the Mach numbers for the collisionless shock of Fig. 1 are remarkably high $(M_{\rm ms} = V/V_{\rm ms} = 15)$, and $M_A = V/V_A = 21)$, and this event is probably one of the highest Mach number collisionless shocks for which any in situ observations are available.

Before comparing plasma wave measurements for the relatively well-defined dayside bow shock crossings at Saturn, Jupiter, Earth and Venus, we discuss characteristics of the outbound bow shock encounter with Saturn on the nightside

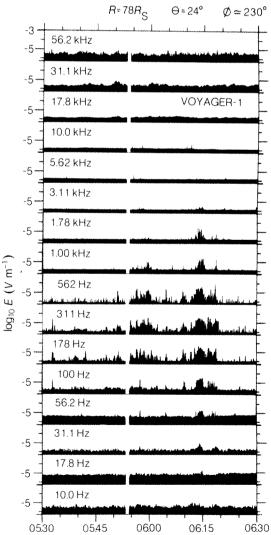

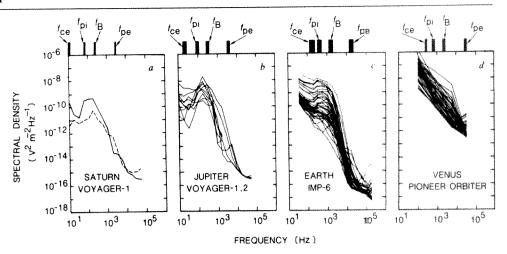

Fig. 2 Sixteen-channel measurements of plasma wave amplitudes at the diffuse outbound crossing of the bow shock. Here, the 10-56 kHz waves are Saturn radio emissions, and the gap between 05.53:23 and 05.54:11 corresponds to an interval when the Voyager tape recorder was acquiring waveform data.

Fig. 3 Multi-planet comparison of plasma wave spectra. a Was constructed amplitude 16-channel the measurements of Figs 1 and 2. The solid and dashed spectra represent the inbound and outbound crossings, respectively. The characteristic frequencies shown at the top are the electron cyclotron frequency (f_{∞}) , the ion plasma frequency (f_{pi}) , the Buneman mode frequency (f_B) , and the electron plasma frequency (f_{pe}) . Although the spectra for Earth (c), Jupiter (b) and Saturn (a) all have a primary or secondary peak in the noise spectrum between f_{pi} and $f_{\rm B}$, the intense low frequency enhancement which is evident in most terrestrial spectra and all the Venus observations is not found at Jupiter or Saturn.

almost midway between local midnight and dawn. During the interval 05.50 to 06.18 on 16 November when Voyager 1 was at $78 R_s$, the spacecraft traversed a relatively diffuse transition layer separating the magnetosheath from the solar wind. Figure 2 shows the relative thickness of the outbound shock and the variability in the plasma wave amplitude profiles; this is characteristic of a quasi-parallel shock configuration that is usually associated with an extensive region of upstream disorder, and it seems that after 06.18, much turbulence was present for an extended period. Ness et al.6 noted the elevated r.m.s. magnetic field noise levels which indicate that enhanced low frequency electromagnetic wave activity was present after 06.18. The plasma wave instrument was able to detect Saturn-associated bursts of ion acoustic waves and electron plasma oscillations out to at least early December more than 400 Rs away from Saturn. These results are readily understandable because at 9.5 AU, the Parker spiral model leads to an average interplanetary field oriented almost perpendicular to the Saturn-Sun line. Thus, the Saturn 'upstream region' or 'foreshock', which can develop when the B-field intersects the shock surface, was encountered after closest approach rather than before.

Planetary bow shock turbulence spectra

Pioneer Venus Orbiter provided the first data on plasma wave activity at the bow shock of a planet other than Earth in December 1978, and in March and July 1979, the Voyager spacecraft transmitted corresponding information from Jupiter's bow shock. Following the 1980 Voyager 1 encounter with Saturn, it is possible to present a preliminary comparison of wave-particle interactions at four planetary bow shocks, but a comprehensive analysis must await Voyager 2 Saturn data.

The IMP-6 study of Rodriguez and Gurnett⁷ serves as a reference for analysis of plasma waves at the terrestrial bow shock, and Fig. 3c shows the average electric field spectra detected at 36 representative crossings of the shock surface. For these crossings, the average solar wind density was 5.2 particles cm⁻³, and the average magnetic field strength was 7.5 nT; these values yield a mean electron plasma frequency ($f_{\rm pe} = 9,000 \sqrt{N}$) of 20.5 kHz, an ion plasma frequency ($f_{\rm pi} = 210\sqrt{N}$ for protons) of 480 Hz, and an electron cyclotron frequency ($f_{\rm ce} = 28B$) of 210 Hz. These characteristic frequencies, along with the 1.65 kHz value that is appropriate for the corresponding Buneman mode⁸ characteristic frequency, $f_{\rm B} = [m_{\rm e}/m_{\rm i}]^{1/3} f_{\rm pe}$ are marked at the top of Fig. 3.

Rodriguez and Gurnett studied how the plasma wave spectrum varied with changes in Alfvén and sonic Mach numbers, plasma β -value ($\beta = 8\pi NK[T_e + T_i]/B^2$), ion temperature, electron-to-ion temperature ratio, solar wind density and shock normal angle. Plots of the mid-frequency (200 Hz-4 kHz) Efield amplitude against T_e/T_i showed a strong positive correlation, and a weaker one when the low frequency (20 Hz-200 Hz) E-field amplitude was used, but the extreme shapes of the shock spectra shown in Fig. 3c were not discussed in association with any particular groups of upstream plasma

parameters. Indeed, as the upstream parameters associated with the Rodriguez and Gurnett data set varied over a huge range $(0.5 \le N \le 19 \text{ cm}^{-3}, 2 \le B \le 17 \text{ nT}, 1.5 \le M_A \le 26.6, 0.03 \le \beta \le 4.5)$, there was no a priori reason to expect to find characteristic changes in shock spectra as we moved inward towards Venus or out to Jupiter and Saturn. Nevertheless, Fig. 3a, b, d strongly suggests that the bow shock spectra at the other planets differ significantly from those detected at Earth.

The 48 Venus spectra on Fig. 3d have been discussed elsewhere⁹: these spectra are limited because the Pioneer Venus instrument has only four filter channels and it uses short antennas which are affected by spacecraft interference. Nevertheless, the shock processes at Venus seem to generate much higher levels of low frequency ($f \le f_{\rm pi}$) plasma wave turbulence than do the corresponding processes at Earth [we use $N({\rm Venus}) = (12 \pm 4)$ electrons cm⁻³ and $B({\rm Venus}) = (10 \pm)$ nT to compute the characteristic frequencies shown at the top of Fig. 3d].

Recently the nine jovian spectra shown in Fig. 3b have been compared with the IMP-6 data¹⁰. The Voyager 1 and 2 measurements were all obtained during the dayside inbound passes, and the characteristic frequencies shown at the top correspond to $N \approx (0.225 \pm 0.075)$ electrons cm⁻³ and $B \approx$ (0.8 ± 0.2) nT. The low frequency enhancement in electric field intensity, evident in most of the terrestrial wave spectra and all of the Venus observations, was not present at Jupiter. Assuming that these low frequency waves represent whistlers, it was speculated that whistler-mode noise may not be as important the jovian bow shock as at Earth and Venus. Alternatively, the Jupiter spectral peaks at higher frequencies could be attributable to plasma conditions in the distant solar wind that yield enhanced generation of ion acoustic or Buneman mode oscillations, rather than suppressed levels for the whistlers.

Figure 3a shows the Voyager 1 Saturn bow shock spectra derived from the measurements of Figs 1 and 2; the solid lines connect one-minute averages for the inbound crossing, and the dashed lines refer to the outbound case. The Jupiter and Saturn shock spectra are quite similar and both have intensity peaks near the $f_{\rm pi}$ and $f_{\rm B}$ characteristic frequencies. It is difficult to identify these wave modes, however, as ion acoustic waves have phase speeds small compared with the solar wind speed; thus, Doppler effects could account for large frequency shifts, and these waves may have $f \leq f_{\rm pi}$ in the solar wind rest frame. As the heliocentric distance increases, there appears to be a significant and consistent variation in the average bow shock turbulence, and we should therefore examine how some relevant interplanetary parameters vary from one planetary orbit to another.

A complete investigation of the variations in bow shock microstructure requires comparative study of the electron and ion temperatures, thermal anisotropies, heat flux moments, and distribution function shapes, as well as comparison of the macroscopic upstream parameters such as magnetic field vector, solar wind velocity, and wind density. Note that the average spectra shown in Fig. 3 can be associated with changes in average

Mach number. Specifically, using $M_A = V/V_A$ and $V_A =$ $(B/(4\pi Nm_+^{1/2}))$, the mean B and N values cited above give $M_A(\text{Venus}) = 6.3$, $M_A(\text{Earth}) = 5.6$, $M_A(\text{Jupiter}) = 11$, and $M_A(Saturn) = 21$. This suggests that there may be a relation between Mach number and spectral shape.

Support for this speculation comes from reanalysis of the IMP-6 bow shock observations. Although the result is not strongly evident in Fig. 3c, three of these spectra have 'outer planet' shapes in the sense that for these cases, the wave level at $f \approx 100 \text{ Hz}$ is much lower than the level at f = 100-1,000 Hz. These peaked terrestrial spectra were detected when the upstream conditions yielded a subset of high Mach numbers (P. Rodriguez, personal communication), and this tends to support a hypothesis that the Jupiter and Saturn shock spectra have unusual characteristics, primarily because the solar wind Mach numbers at the outer planets tend to be much higher than the customary values near 0.7-1.0 AU.

Discussion

On theoretical and experimental grounds it is known 11,12 that several distinct dissipation mechanisms develop in collisionless shocks and that the dominant interaction depends strongly on the Mach number. For low Mach numbers $(M \le M^* \approx 2-3)$, the shock is resistive, and for $M > M^*$, viscous dissipation becomes

important. Above a second critical Mach number, $M^{**} \approx 6-7$, theory¹¹ requires other types of dissipation, but these very high Mach number shocks have not been intensively analysed. We now find that upstream conditions at the outer planets generally yield Mach numbers considerably higher than M^{**} , and thus it is of great interest to find that the Jupiter and Saturn bow shock crossings have plasma turbulence spectra that resemble those found at Earth when M is high. The Jupiter and Saturn characteristics are also unusual in that the jump in electron temperature across the shock is enormous $(T_e^2/T_e^1 \approx 15 \text{ at Jupiter}^{13})$ and the magnetosheath wave levels are extremely low.

In conclusion, our study of the bow shocks at Jupiter and Saturn has provided insight into collisionless shock microstructure for an important new plasma regime, and helps to understand shocked plasmas of non-equilibrium characteristics that seem to be different from those found in the terrestrial magnetosheath.

Surface waves on Saturn's magnetopause

R. P. Lepping', L. F. Burlaga' & L. W. Klein[†]

* NASA/Goddard Space Flight Center, Laboratory for Extraterrestrial Physics, Greenbelt, Maryland 20771, USA † Computer Sciences Corporation, 8728 Colesville Road, Silver Spring, Maryland 20910, USA

Voyager 1 magnetometer data have shown that small-amplitude surface waves occurred on Saturn's dayside magnetopause, causing multiple inbound crossings of this boundary. These waves were travelling approximately parallel to Saturn's equatorial plane along the magnetopause ('tailward'), suggesting that they were driven by the rotation of Saturn's magnetosphere. Hydromagnetic waves (possibly slow mode) were observed in the adjacent magnetosheath.

ON 11 November (day 316) 1980 at 23.27 UT Voyager 1 crossed Saturn's bow shock on its inbound trajectory towards the planet. This was followed by a series of five, fairly regularly spaced magnetopause (MP) crossings ending at ≈ 02.47 UT of day 317, and discussed in a preliminary report¹. The analysis and interpretation of the magnetometer data taken over this ≈ 3.5-h period is now discussed in terms of the first observations of surface waves on Saturn's magnetopause, their characteristics, and a plausible connection between the magnetopause and hydromagnetic waves occurring in the magnetosheath.

Observations

The dual three-axis low field magnetometer system onboard Vovager 1 was in its most sensitive range of 0.0043 nT per quantization step for the entire period of interest. The measurements, at 0.060-s intervals, were probably accurate to ±0.03 nT per axis. The magnetometer experiment is described in detail elsewhere². Figure 1 presents 9.6-s averages of the magnetic field and shows the inbound bow shock, five magnetopause crossings, and the intervening magnetosheath. The inset shows the trajectory of the spacecraft projected on the orbital plane of Saturn; in the inbound magnetosheath the spacecraft was only about 10° below this plane (in a Saturn centred system). The two outstanding characteristics in the data are: (1) large quasi-periodic oscillations in magnitude (B) of the field in the magnetosheath that seem to grow in amplitude

from the bow shock to the MP; (2) fairly regularly spaced MP crossings.

Table 1 lists the centre times and durations (Δt) for the five MP crossings. The field latitudes are $\langle \delta \rangle \approx -75^{\circ}$, on the magnetosphere side of each crossing, as expected for Saturn's distant front-side magnetosphere 1.3, and the field shows , and the field shows moderate draping at medium (positive) latitudes in the magnetosheath near the MP. That is, the magnetosheath field near the MP boundary is apparently being constrained to lie parallel to the MP as it is convected along the boundary. At more distant locations from the MP the magnetosheath field is closer to $\delta \approx 0^{\circ}$ at $\langle \lambda \rangle \approx 285^{\circ}$. The directional changes of the field across the MPs were large, permitting an accurate estimation of the normal to the MP surface for each crossing.

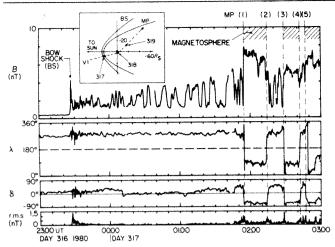

Fig. 1 Voyager 1 magnetic field (9.6 s) averages for 4 h around Saturn's inbound magnetosheath in terms of field magnitude B, longitude λ , latitude δ , and pythagorean r.m.s. deviation. The angles λ , δ are expressed in a heliographic, spacecraft centred, coordinate system, such that $\lambda = \tan^{-1} (B_T/B_R)$ and $\delta = \sin^{-1} (B_N/B)$, where: $\hat{\mathbf{R}}$ is radially away from the Sun; $\hat{\mathbf{T}}$ is parallel to the Sun's equator plane, normal to $\hat{\mathbf{R}}$, and positive in the general direction of Saturn's orbital motion; and $\hat{\mathbf{N}} = \hat{\mathbf{R}} \times \hat{\mathbf{T}}$. At this time $\hat{\mathbf{N}}$ is parallel to the ecliptic plane normal within $\sim 2^\circ$. The five inbound magnetopause crossings are labelled. The day numbers in the trajectory insert refer to spacecraft positions at the start of the referred day, and $R_s = 60,330$ km, Saturn's radius.

Analysis of the magnetopause

Two methods were used to estimate normals to the MP for comparison purposes. The first uses a variance analysis of difference fields (ΔB_i) across the discontinuity and assigns the normal direction (δ_N, λ_N) to the minimum variance direction; $\Delta \mathbf{B}_i = (\mathbf{B}_i - \langle \mathbf{B} \rangle)$, \mathbf{B}_i is one of the series of 1.92-s averages (in our case) occurring in the analysis interval across the MP, and $\langle \mathbf{B} \rangle$ is the average of the Bis. The second method is similar to the first but uses the full vectors, B_i (1.92-s average fields); then the minimum variance direction of the Bis is the estimated normal direction (δ_n, λ_n) (see Table 1). The angle η is defined as \cos^{-1} $(B_z/\langle B \rangle)$, where B_z is the component of $\langle B \rangle$ along the estimated normal, according to method (1), and $\langle B \rangle$ is $|\langle \mathbf{B} \rangle|$. When $\eta = 90^{\circ}$ the MP discontinuity is described as a tangential discontinuity. Within the expected errors on the η s all crossings can be considered as tangential discontinuities; this is also common for the Earth's dayside MP. When the MP is a tangential discontinuity and when magnetometer zero level errors can be ignored, method (2) yields more accurate normal estimates than method (1) (ref. 6). Only the results of method (2) will be used in our surface wave analysis. However, both methods qualitatively show the same main features: oscillations in both δ and λ , and almost the same overall averages.

Both methods indicate that surface waves were occurring on the MP surface, just as have been seen to occur on the Earth's MP^{7,8}. The nature of these waves is more evident in a more appropriate coordinate system. The variance analysis of method (2) applied to the normals shows that a maximum variance plane lies parallel to Saturn's equatorial plane within $\sim 10^{\circ}$. This suggested transforming the normals to a Saturn equatorial system, similar to the δ , λ (heliographic) system, except that Saturn's equatorial plane replaces the Sun's equatorial plane. This requires a 26° rotation about the Saturn-Sun line. Table 1 also shows the transformed method (2') normals (δ_{eq} , λ_{eq}). The oscillation in the latitude (δ) of the normals has now disappeared, as expected; by comparing method (2) and (2') normals in Table 1 we note how r.m.s. (δ) has decreased and r.m.s. (λ) has increased. Apparently the surface wave propagation vector is directed along the MP in Saturn's equatorial plane within $\approx 10^{\circ}$. The transformed estimated normal longitudes (λ_{eq}) are now used to analyse this surface wave⁷.

Magnetopause surface wave analysis

The surface wave model assumes that the wave is two-dimensional, transverse, and composed of two partial sinusoids which

must match in location, slope, and wave speed at their common point; the wave vector is locally parallel to the zeroth-order MP given by an earlier model1. A second assumption is that the observed MP crossings are due entirely to the passing wave, and not to large scale radial motion of the MP. The eight quantities to be estimated are: A_i , the amplitude of the i-part of the wave; α_1 , the phase of the *i*-part; λ_i , the wavelength of the *i*-part of the wave; $V_{\rm w}$, the phase speed of the wave, assumed constant for the full wave; and yo, the zero-displacement line of the wave, where i = 1, 2. The slopes and wave displacements at the two end points of the wave and at the common point between them must match observations, providing eight equations to solve. These three points occur at three successive MP crossings. The input quantities are: V_N , V_T , the components of the velocity of the spacecraft normal and tangential to the zeroth-order MP, respectively, in Saturn's equatorial plane; $\tan \theta$ (where $\theta = \lambda_{eq}$ - λ_0), the slope of the MP as estimated by the minimum variance analysis; and the times of the three successive MP crossings. The input (centre) times are given in Table 1, $V_N = 16.6 \text{ km s}^{-1}$ $V_T = 2.4 \text{ km s}^{-1}$. The components of the spacecraft's velocity (V_N, V_T) as well as the derived wave speed (V_W) are measured in a system fixed with respect to the Saturn-Sun line. The angle λ_0 is the longitude of the normal to an ideal zeroth-order MP in the locality of the three successive crossings. Three trial λ_0 s were used (197°, 200° and 202°) giving three trial sets of tan θ for the given λ_{eq} s. The λ_0 s are consistent with an estimated λ_0 of $200^{\circ} \pm 3^{\circ}$ based on a weighted average of a model normal (λ_0 (model) = 208°) and the average of the derived λ_{eq} s from Table 1 (195°), where the latter was favoured by 2-to-1 in the weighting. Three separate (but not independent) analyses were made of the wave characteristics using: MPs 1, 2 and 3 (Set I); MPs 2, 3 and 4 (Set II); and MPs 3, 4 and 5 (Set III).

Table 2 gives the results of the surface wave calculations, where A_e is the effective wave amplitude based on a weighted average of A_1 and A_2 , similarly for the effective wavelength λ_e and $\tau_e = \lambda_e/V_w$; (for the method of weighting see ref. 7). The five trial results not shown ($I_{1,2,3}$ and $I_{1,2,3}$) were not physically allowable. Regardless of the variability of V_w , A_e and λ_e , the effective period τ_e is consistently 23 \pm 2) min and λ_e/A_e is nearly constant at 10 (\pm 1). The latter fact indicates that the wave displacement is apparently of relatively small amplitude,

We now check the assumption that the MP crossings were primarily due to the surface wave and not to bulk normal motion of the MP. The time between centres of the first and last crossings is 52 min. Then $\langle A_e \rangle \approx \Delta T \times V_{\rm N}/2$, which is 26,000 km; the wave analysis gives a very favourable comparison of $\langle A_e \rangle = 25,600$ km (Table 2).

Simple geometrical considerations give an MP thickness

$$D = |\Delta t[(V_{\mathbf{W}} - V_{\mathbf{T}})\sin(\lambda_{\mathbf{eq}} - \lambda_0) + V_{\mathbf{N}}\cos(\lambda_{\mathbf{eq}} - \lambda_0)]|$$
 (1)

for each crossing. All quantities in equation (1) are fairly accurately estimated, measured, or known, except λ_0 and $V_{\rm W}$, which were moderately well estimated. We assume $V_{\rm W}$ to be $180~{\rm km~s^{-1}}$, the average of the four estimated cases (Table 2). The Δts and $\lambda_{\rm eq}s$ are given in Table 1. Consistent with our choice

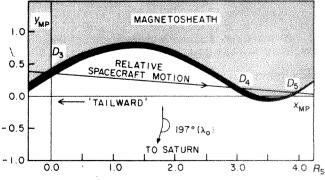

Fig. 2 An average example (case III_1) of Saturn's magnetopause surface waves. The unperturbed magnetopause is aligned with the X_{MP} -axis. $D_{3,4,8}$ refer to magnetopause thicknesses.

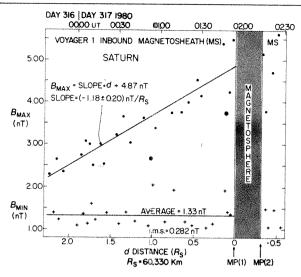

Fig. 3 The relative maximum $(B_{\text{MAX}}, \bullet)$ and minimum $(B_{\text{MIN}}, +)$ magnetic field magnitudes, based on 9.6-s averages, for the inbound magnetosheath regions, as a function of distance (d) from the first magnetopause crossing and time. \bullet , points not used in the straight line fit of B_{MAX} .

of $V_{\rm w}$ we assume that $\lambda_0=197^{\circ}$ and 200°, those giving intermediate wave characteristics. The resulting estimated MP thicknesses range from 2,300 km (crossing 5) to 8,500 km (crossing 2), giving $\langle D \rangle = 5.0 \pm 3.0 \times 10^3$ km, averaged over all five crossings and over both λ_0 s; $\lambda_0=197^{\circ}$ gave the smaller spread of values. Note that $\langle A_e \rangle$ is about five times greater than $\langle D \rangle$, for either λ_0 , consistent with another implicit assumption that the wave amplitude is significantly greater than the MP thickness.

Figure 2 shows the MP surface wave derived from trial III₁ (that is $\lambda_0=197^\circ$) chosen because it most closely resembles the average of all successful trials (Table 2). The variable MP thickness shown is based on $\lambda_0=197^\circ$ for crossings 3, 4 and 5. Such surface waves at this location on the MP (≈ 13.10 LT) near Saturn's equatorial plane are possibly due to a Kelvin–Helmholtz instability⁹ at the boundary, on either side of which plasmas are flowing parallel to it but at significantly different speeds. The difference in speed across the MP in Saturn's equatorial plane must be closely comparable with the wave speed $\langle V_w \rangle$, that is

$$\langle V_{\mathbf{w}} \rangle \approx V(\text{sphere}) - V(\text{sheath})$$
 (2)

if the Kelvin-Helmholtz instability is the causal mechanism. In our case the magnetosphere plasma speed, V(sphere), is faster than the magnetosheath plasma speed, V(sheath). Using an Earth-like magnetosheath model¹⁰ for $M_{\infty}=12$ and $\gamma=5/3$ at 13.10 LT and a typical solar wind speed of 400 km s⁻¹ (close to that actually measured for many hours before the inbound bow shock (J. Scudder, personal communication)), gives $V(\text{sheath})=0.16\times400=64$ km s⁻¹; this estimated magnetosheath speed is not very sensitive to M_{∞} , provided it is ≥ 5 . M_{∞} was calculated to be $\sim 13-15$ where the upstream proton and electron temperatures ($T_p\approx 2.3\times10^4$ K and $T_s\approx 1.5\times10^4$ K) were provided by the Voyager Plasma Science Team. For $\langle V_{\rm W}\rangle=180$ km s⁻¹ and this magnetosheath speed, equation (2) yields $V(\text{sphere})\approx 240$ km s⁻¹. If Saturn's magnetosphere rigidly corotates out to the frontside MP at ≈ 23 $R_{\rm S}$ (where $R_{\rm S}\equiv 60,330$ km, Saturn's

radius) at this time, the corotation speed at the MP would be $230 \, \mathrm{km \, s^{-1}}$, close to the above result. As the uncertainty on our estimate of $V(\mathrm{sphere})$ is probably quite large, we cannot say that rigid corotation of the magnetosphere holds to $23 \, R_{\mathrm{s}}$, but only that this important necessary condition (equation (2)) for showing that the Kelvin–Helmholtz instability may be applicable is not obviously violated. The fact that the MP surface normals oscillate in Saturn's equatorial plane, rather than in a plane containing the local magnetosheath plasma flow (\approx the ecliptic plane), supports the view that it is primarily the magnetosphere motion which drives the instability.

Inbound magnetosheath waves

Here we briefly discuss the oscillations occurring in the inbound magnetosheath field, mainly in its magnitude, B, as shown in Fig. 1; these have an average period of ~ 6 min. as measured in the spacecraft frame of reference. The latitude $(\langle \delta_B \rangle \approx 0^\circ)$ and longitude $(\langle \lambda_B \rangle \approx 285^\circ)$ of the magnetosheath field agrees with an expected wrapped-up solar wind field at Saturn's orbit $(\lambda_B \approx 270^\circ \text{ or } 90^\circ)$. Oscillations in field direction, especially in longitude, are present, but dominated by the magnitude changes. The values of the local maxima and minima of the field in the magnetosheath are plotted in Fig. 3 against normal distance from the first MP(1), assuming a stationary zeroth-order MP at this time and using the spacecraft speed normal to the MP of $V_N = 16.6 \text{ km s}^{-1}$. Straight line fits were made to the B_{MAX} and B_{MIN} points; the B_{MIN} set was assumed to have zero slope. The wave has apparent amplitude (A) growth given by

$$A = (B_{\text{MAX}} - B_{\text{MIN}})/2 = \text{slope} \times d/2 - 1.77 \text{ nT}$$
 (3)

where slope = (-1.18 ± 0.20) nT/ $R_{\rm S}$ according to the straight-line fits. The marked growth in amplitude as the MP is approached suggests that the MP may be the source of these waves; notice the highest $B_{\rm MAX}$ amplitudes were maintained in the magnetosheath even when the spacecraft returned there between ≈ 02.15 and 02.30 UT. Similar waves in the inbound Pioneer 11 magnetosheath data were reported by Smith et al.³. The Pioneer observations, however, differed in one respect: the $B_{\rm MIN}$ s did not remain nearly constant but grew approximately in line with the $B_{\rm MAX}$ s, yielding $A\approx$ constant. The apparent difference is either a different phenomenon or simply due to different conditions, such as possibly an outward moving MP in the Pioneer 11 case and a static (excluding surface waves) MP for Voyager. In any case, a gradual increase in B is probably not needed to produce the waves.

Examination of the Voyager plasma science electron data (E. Sittler, personal communication) for the period shown in Fig. 3 indicates that the electron density was $\sim 180^\circ$ out-of-phase with B for these waves, suggesting that they are slow mode magnetosonic waves, which have their most rapid phase velocity along the ambient magnetic field. If the MP is the source of these waves, they must have a component of their propagation vector upstream, and it must be greater than the incoming convected magnetosheath plasma velocity; this is possible, because at this location the magnetosheath plasma is subsonic. Although the waves in B resemble solitons³, β in the magnetosheath is large, so a large perturbation in B does not necessarily imply a correspondingly large change in density.

Summary and discussion

Voyager 1 magnetometer data have revealed that surface waves occur on Saturn's dayside MP. Estimates of Saturn's magnetopause wave properties show that: the wave speed is 180 ± 90 km s $^{-1}$, amplitude $12-50\times10^3$ km (or $\sim0.5~R_{\rm S}$), wavelength $1-5\times10^5$ km (or $\sim5~R_{\rm S}$), and a well determined period 23 ± 2 min. Most estimates yielded a consistent ratio of wavelength-to-amplitude of 10 ± 1 , and a typical magnetopause thickness of $5.0\pm3.0\times10^3$ km or $\sim0.1~R_{\rm S}$ was determined.

The success of the model was partly due to the large-scale stationarity of the MP during the analysis period, probably the result of apparently persisting quiet upstream solar wind conditions, which was the case before the inbound bow shock cross-

ing. The occurrence of only a single bow shock crossing shortly before the multiple MP crossings is consistent with our basic premise that the surface waves caused the multiple crossings at a time when the solar wind was fortuitously quiet.

Hydromagnetic waves occurring in magnetosheath and having an average period in the spacecraft frame of reference of 6 min grew markedly in amplitude as the magnetopause was approached. This suggests the MP as a

Saturn's magnetic tail: structure and dynamics

K. W. Behannon, J. E. P. Connerney & N. F. Ness

Laboratory for Extraterrestrial Physics, NASA Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

Voyager 1 magnetic field observations have provided evidence of a saturnian magnetic tail. Tail current system distributions are inferred through comparison of the observations with a realistic magnetotail current system model. Temporal variations observed in the tail were probably produced by solar wind variations.

SATURN'S magnetic tail was first observed by Voyager 1 as it tranversed the saturnian magnetosphere outbound at 03.40 LT. The observed magnetic field directions clearly indicated the sweeping back of field lines into a tail configuration pointing away from the Sun¹ and led us to conclude that Saturn, like Earth and Jupiter, possesses a magnetotail that develops in the interaction of the solar wind with the planetary magnetic field. Closest approach for Voyager 1 at Saturn occurred at 23.45 UT on 12 November 1981. Between 17.29 and 21.52 UT on 14 November, it crossed the magnetopause outbound five times at an average distance from Saturn of 45 R_s (24 R_s antisolar distance, where R_s = Saturn radii = 60,330 km) and at a latitude ~24° (ref. 1). The encounter trajectory characteristics, together with the length of time (~45 h) spent in the night-side magnetosphere, gave ample opportunity to study the geometry of the tail. We estimated the tail diameter to be $\sim 80 R_{\rm s}$, less than that of the jovian tail by a factor of 4-6. From the observed size of the tail and the average magnitude of the distant tail lobe field that was measured (~3 nT), a conservation of flux argument gave an estimate of 11°-15° for the half-angular size of the saturnian polar cap auroral zone, smaller than that of Earth¹. Because of the high latitude of the outbound pass, there were no traversals of the tail current sheet. Only the northern lobe field (directed away from the planet) was measured. The near alignment of Saturn's magnetic dipole and rotational axes made the outbound traversal a nearly constant magnetic latitude path through a planetary magnetosphere.

Although there was no direct tail current sheet observation, plausible current distributions and geometry can be inferred through comparison of measurements with the fields calculated from simple but realistic magnetosphere models that include magnetotail current systems. The preliminary results of the study of one such model are described below.

Model magnetosphere

We have studied a model of Saturn's magnetosphere which is consistent with the Voyager 1 magnetic field observations but which must also be non-unique. A noon-midnight meridian projection of the model field and the Voyager 1 outbound hourly averaged magnetic field observations is shown in Fig. 1. The closure of the tail field lines is very sensitive to the detailed current distribution in the more distant (and unexplored) tail and is not a direct result of the fit to the magnetic field observations. It is, rather, a boundary condition imposed on this model determined, in part, by the observed electron pitch angle distributions² which are indicative of closed field lines. The closure of field lines in the tail is uncertain. Observations of solar cosmic rays to 9 R_s by the Pioneer 11 cosmic ray experiment suggest open field lines in the magnetotail, although Saturn's magnetosphere was in a disturbed state during the Pioneer 11 encounter.

The model field has the following components: an internal dipole field of $0.21 \,\mathrm{G} - R_{\mathrm{S}}^3$ aligned with z_{SM} ; a distributed near-equatorial disk or ring current in the region $8 < \rho < 16 R_s$; cross-tail currents extending from $x_{SM} = -16$ to $-100 R_S$, closing on the magnetopause boundary; and confinement of the day-side magnetosphere by image dipoles. The azimuthal ring current at Saturn is modelled on a similar structure at Jupiter and will not be discussed here. The field of the cross tail currents

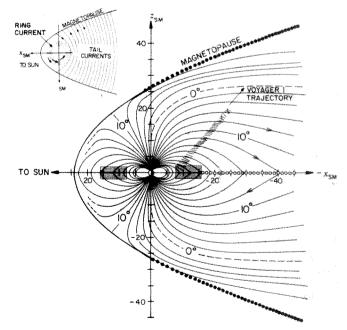

Fig. 1 Conceptual and quantitative model of Saturn's magnetosphere in the noon-midnight meridian plane. Field lines are drawn for 2° increments of invariant latitude. Azimuthal disk or ring current (stippled) is indicated, as well as model cross-tail currents closing on the magnetopause boundary. Projections of Voyager 1 outbound hourly-averaged magnetic field observations onto the solar magnetospheric (SM) x-z plane are also shown. Insert, model cross-tail currents in the SM x-y plane. Current flows eastward in parabolic paths to the magnetopause (MP) pause boundary and closes in planes of constant x equally on both the northern and southern lobe MP

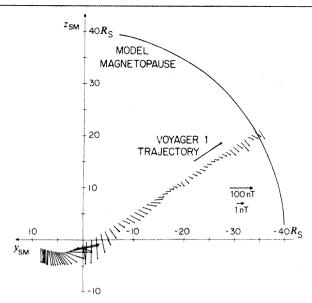

Fig. 2 Projection of hourly-averaged magnetic field components in the saturnian magnetosphere onto the SM y-z plane along the projected Voyager 1 trajectory. A logarithmic scale has been used to represent field magnitude as indicated.

is computed numerically by summation of the field due to a system of individual closed current loops similar to that used in models of the Earth's magnetosphere ^{5.6}. Individual loops are spaced at $1-R_{\rm S}$ intervals and carry an eastward current in the solar magnetospheric (SM) equatorial plane as indicated in Fig. 1. The SM coordinate system is a right-handed, orthogonal, non-rotating system defined such that $\hat{x}_{\rm SM}$ is directed from the planet to the Sun and the $\hat{z}_{\rm SM}$ axis lies in the plane formed by $\hat{x}_{\rm SM}$ and \vec{M} , the magnetic dipole of the planetary field. The current has a $1/(x_{\rm SM})^{1/2}$ dependence, decreasing from $\sim 5~{\rm A~km}^{-1}$ at $x_{\rm SM}$ of $-16~R_{\rm S}$, which is about half the (linear) current density of the distributed ring currents at their outer edge.

In this view of Saturn's magnetic tail, the high latitude field lines observed along most of the Voyager 1 trajectory remain closed, while the observed magnetic field orientation along the trajectory remains essentially parallel to the SM equatorial plane. The estimated size of the polar cap¹ based on the conservation of flux using an estimate of 3 nT for the tail field at $x_{\rm SM} = -25$ may represent an upper limit on the size of the polar cap. As indicated in Fig. 1, to the extent that field lines cross the equatorial plane at greater $-x_{\rm SM}$, Saturn's polar cap may be smaller and is not symmetric with respect to the dusk meridian.

A consequence of the confinement of Saturn's magnetosphere to a parabolic magnetopause boundary is the very Earth-like day-side cusp at $\sim 80^{\circ}$ invariant latitude. The inferred source region of Saturn kilometric radiation (SKR) is centred about the intersection of the noon-midnight meridian and 80° invariant latitude. This suggests that SKR is related to particle precipitation in the cusp, analogous to the terrestrial kilometric radiation associated with the Earth's polar cusp⁸.

Tail dynamics

Variations of the magnetotail magnetic field were observed by Voyager 1 during the outbound traversal¹; they appear as moderately small amplitude, long-period excursions in field direction and magnitude. The directional variations can be seen in the hourly average SM y-z plane vector projections of Fig. 2. The x-y and x-z plane projections have been presented previously¹. Assuming that the observed changes are most likely temporal and not spatial, is the source of these perturbations of the tail lobe field internal or external to the magnetosphere? Quasiperiodic variations of the flux of low energy charged particles were also observed during this period², and a Saturn-related magnetic anomaly-type feature suggested as the cause.

The magnetic field measurements have been analysed to try to elucidate the source location of the perturbations producing the

observed variations. To test the possibility of an internal, planet-associated (and hence periodic) source, hourly values of the magnetic field direction angles λ and δ have been plotted against sub-spacecraft Saturn longitude in superposed epochs for the 36-h period when Voyager 1 was at a radial distance $r > 10~R_{\rm S}$ (Fig. 3). Here λ and δ are the SM azimuth and latitude angles, respectively, of the field. Because the dipole tilt relative to the rotation axis is $\sim 1^{\circ}$, SM coordinates are defined for Saturn such that λ is measured anticlockwise in the magnetic dipole equatorial plane, as viewed from north of (above) the plane, with the $\lambda=0^{\circ}$ meridian plane at local noon.

The data suggest a recurrence tendency at roughly the planetary rotation rate, but with changes evident in the amplitude and phase of the variation. Note that Voyager 1 was in the tail lobe for only $\sim 2-1/2$ planetary rotation periods, and it is therefore difficult to establish a recurrence pattern. If recurrence is assumed, a period of 12.1 h is obtained for the field variation, significantly greater than the 10.66 h planetary rotation period deduced by the Voyager 1 Planetary Radio Astronomy experiment. The longer period seen at Voyager 1 may be caused by Doppler-shifting of the perturbation signal as it 'propagates' like a wave from Saturn. Taking into account the velocity of Voyager 1 relative to Saturn, a radial wave speed $V_r \approx 140 \text{ km}^{-1}$ is obtained.

This wave speed can be tested for consistency with the Alfvén speed $V_A = B/(4\pi mn)^{1/2}$ expected in the tail lobe plasma. The ion number density, n, is assumed to be equal to that reported for the plasma electrons¹⁰. At distances $r = 10 R_s$ and $40 R_s$, respectively, field magnitudes of 21 and 3 nT and densities of 0.3 and $0.003\,\mathrm{cm^{-3}}$ were measured. Assuming the ions are protons gives $V_A = 836 \text{ km s}^{-1}$ in the near tail, increasing to 1,196 km s⁻¹ in the distant tail. If the ions were nitrogen, these values would decrease to 316 and 452 km s⁻¹, respectively. The V_A values for a nitrogen plasma are factors of more than 2-3 higher than the Doppler-shift predicted wave speed of 140 km s⁻¹ and factors of 6-8 too high in the case of hydrogen. Conversely, assuming $V_A = 140 \text{ km s}^{-1}$ predicts densities for hydrogen and nitrogen of $n_H = 10.7 \text{ cm}^{-3}$ and $n_N = 1.5 \text{ cm}^{-3}$ at $r = 10 R_{\rm s}$ compared with the observed $n_{\rm e} = 0.3 \,{\rm cm}^{-3}$, and $n_{\rm H} =$ 0.22 cm^{-3} and $n_N = 0.03 \text{ cm}^{-3}$ at $r = 40 R_S$ compared with $n_e =$ 0.003 cm^{-3} .

These results indicate an inconsistency between the observations and the hypothesis of a planet-associated propagating wave. Furthermore, because the magnetic dipole axis tilt relative to the axis of rotation is estimated to be in the order of only 1°, the dipole wobble is unlikely to produce the observed variations.

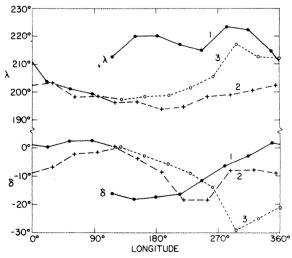

Fig. 3 Superposed epoch presentation of hourly values of magnetotail magnetic field azimuthal (λ) and latitude (δ) angles as functions of planetary longitude for three successive rotations of the planet (1, 2 and 3). The data do not demonstrate clearly a longitude-based recurrence pattern.

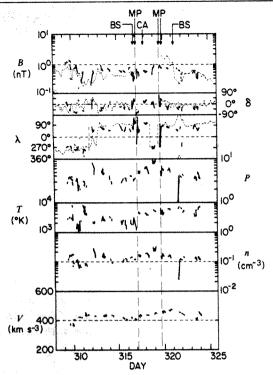

Fig. 4 Predicted solar wind parameters and interplanetary magnetic field during the Voyager 1 encounter period. These data were derived from the solar wind measurements by Voyager 2 upstream of Saturn (see text). Plasma parameters shown include bulk speed (V); number density (n); temperature (T); and plasma pressure (P). The magnetic field is given in terms of its magnitude, B, and the heliographic latitude and azimuthal angles, δ and λ . Actual Voyager 1 measurements are also given (dashed curves). Voyager 1 magnetopause (MP) crossing times are given by arrows at top and further delineated by vertical lines. Bow shock (BS) crossings and closest approach (CA) times are also indicated by arrows at the top.

An investigation of the solar wind during the encounter period indicates that perturbations outside the saturnian magnetosphere may have been the source of the observed variations. The solar wind and interplanetary magnetic field (IMF) conditions at Saturn during the encounter have been predicted by applying a transformation to Voyager 2 interplanetary hourly average field and plasma observations (J. D. Sullivan and H. S. Bridge, personal communication). This projects the observations in two-dimensional space and in time assuming that each parcel of plasma expands radially outward at constant speed. The hourly averaged data propagated in this way from Voyager 2 to Saturn are shown in Fig. 4. Time is given as day-of-year number (day 317 = 12 November). The distorted and fragmented appearance of the data is due to effects of the variable speed correction applied in time-shifting each parcel and the intermittent tracking and data retrieval from Voyager 2. The sizeable gaps (~14 h) mean that a one-to-one correlation between changes in these data and those seen by Voyager 1 inside the saturnian magnetosphere is impossible. However, the data show substantial changes in the solar wind and IMF during the encounter. The lighter dashed data curves superimposed on the predicted data in the top three panels are the actual Voyager 1 IMF observations for comparison. The field data are in spacecraft-centred heliographic coordinates, a spherical system with azimuth $\lambda = \tan^{-1} (B_T/B_R)$ and $\delta = \sin^{-1} (B_N/B)$. where \hat{R} is radially away from the Sun; \hat{T} is perpendicular to \hat{R} and parallel to the solar equatorial plane, positive in the general direction of Saturn's orbital motion; and $N = R \times T$.

An examination of λ shows a prediction of an IMF sector transition occurring ~6 days before closest approach (CA) and a similar, return transition occurring between 7 and 16 h after CA. These are accentuated by vertical dashed lines at the midpoints of the gaps in the λ data where the transitions occurred. In the latter transition, which would have taken place while Voyager 1 was in the tail, the new state of the medium only persisted for between 10 and 32 h and thus was either a very narrow sector or a filamentary-type structure. The field magnitude increased within this region, accompanied by a plasma density increase of about a factor of two and a corresponding increase in solar wind pressure. The leading edge of this region is predicted to have passed between the middle and the end of day 318—the period when the temporal excursions in the magnetotail began.

The major uncertainty is that the Voyager 2 data are being extrapolated over a distance of ~1.7 AU, and in that distance the characteristics of plasma streams and associated IMF structures can be modified significantly by dynamical processes. A comparison of the projected Voyager 2 data with measurements from Voyager 1 before and after passing through Saturn's magnetosphere (included in Fig. 4) confirms the essential features of the prediction. However, the sector transition predicted to occur at the end of day 311 was actually observed to begin ~12 h later. A similar shift in the onset of the perturbations during tail passage would start their effect at a later time but with Voyager 1 still in the magnetotail. Different transformation conditions (higher solar wind speed) could have produced a closer agreement in this case between predicted and observed features than was found during the earlier, pre-encounter period.

While the direct consequences for a magnetotail orientation and field strength of changes in external solar wind direction and pressure on the boundary are generally understood, how changes in the IMF configuration influence a magnetotail is not completely understood. Studies of the terrestrial magnetosphere show that this influence is probably exerted in most cases indirectly through a chain of events controlled by the IMF-tomagnetospheric field reconnection efficiency and including the process of flux transfer within the magnetosphere 11,12. Because the observations at Saturn are limited to one tail lobe, and because of the supporting interplanetary measurements, we can show only that plausible conditions existed in the interplanetary medium for stimulating the observed tail perturbations, with the precise mechanism remaining a matter of speculation. As an internal source mechanism for the perturbations seems inconsistent with measured physical parameters, we conclude that an external source, the solar wind, is responsible.

We thank our Voyager plasma investigation colleagues at MIT for providing the projected Voyager 2 plasma and magnetic field data for use as a prediction of solar wind conditions at Saturn during the Voyager 1 encounter.

† ICI Corporate Laboratory, The Heath, Runcorn, Cheshire WA7 4QE, UK

A 514-base pair fragment of double-stranded DNA coding for human interferon- α_1 (166 amino acid residues), and containing initiation and termination signals plus appropriate restriction enzyme sites for plasmid insertion, has been totally synthesized. The synthesis involved preparation of 66 oligodeoxyribonucleotides, ranging in size from 14 to 21 residues, plus 1 deoxydecanucleotide, by rapid, solid phase procedures, and enzymatic ligation of the oligonucleotides. After ligation of the synthetic gene to a plasmid vector and transformation of Escherichia coli, clones containing the anticipated gene sequence were obtained.

THE antiviral^{1,2}, cell proliferation inhibition³ and immuno-modulating properties⁴ of human interferons (IFNs) have generated great interest because of their potential clinical value in the treatment of viral infections and malignancies. Thorough investigation of the efficacy of both leukocytic (IFN- α) or fibroblastic (IFN- β) interferons has, however, been hampered by an inability to purify large amounts of these proteins from human cells.

The recent application of recombinant DNA techniques has dramatically changed this situation. Several groups have obtained cDNA clones prepared using mRNA from a variety of human cells induced to synthesize interferon(s)⁵⁻¹⁰. DNA sequencing has allowed the amino acid sequences of a number of IFN- α s¹¹ and IFN- β ^{12,13} to be deduced (as well as their putative signal sequences) and various elegant genetic manipulations have generated expression plasmids which direct the bacterial synthesis of biologically active interferons 14-21. A second phase of this research has seen eight or more distinct human leukocyte interferon genes²² identified in human DNA libraries and neither these IFN- α genes^{23,24}, nor the IFN- β gene^{25,26}, apparently contain introns. In some of the above studies the availability of specific oligonucleotides, designed on the basis of limited amino acid sequence data^{27,28}, was invaluable for the identification of cloned IFN cDNA. Furthermore, synthetic oligonucleotides have been generally useful in the various gene editing procedures used for the construction of expression plasmids.

On the basis of the nucleotide sequence of the first cloned human IFN-α cDNA published by Weissmann and co-workers (IFN- α_1), we designed a DNA fragment which would encode the same protein and be amenable to total chemical synthesis (Fig. 1). Such a synthetic gene has several potential advantages, which are discussed further below. However, it is obviously desirable that such a synthesis be accomplished in a comparable time scale with that required for isolation of the gene from natural sources. Various other synthetic genes, including those for human somatostatin²⁹, human insulin A and B chains³⁰ and N^{α} -desacetylthymosin α_1 (ref. 31), have previously been constructed but these molecules are all considerably smaller than the IFNs. Total synthesis of an IFN gene would have been unrealistic using standard solution phase phosphotriester methodology as applied in the above examples³². Recently, we have developed a novel solid phase phosphotriester approach for the synthesis of oligonucleotides^{33,34}. This increases the rate of synthesis by an order of magnitude and is routinely reliable, the inherent hazards of repeated chromatographic purification being largely avoided.

Using these methods, 67 different oligonucleotides containing around 15 nucleotide residues were synthesized. They were separately purified and 5' phosphorylated, then sequentially ligated to yield a 514-base pair (bp) fragment. After insertion in a hybrid plasmid and cloning in *Escherichia coli*, the synthetic

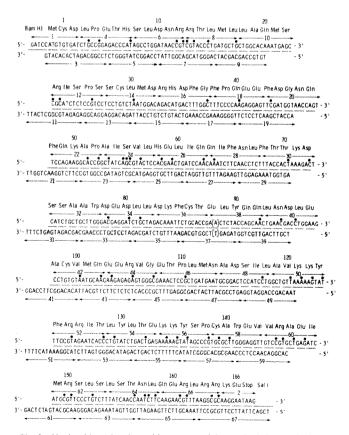

Fig. 1 Nucleotide and amino acid sequence of the synthetic human leukocyte interferon gene. Individual oligonucleotides (1-67) are arrowed. Dots above bases in the coding strand indicate changes with respect to the native sequence⁷. Numbers above each line refer to amino acid position.

gene was characterized by restriction enzyme digests and total sequence determination. Biological activity of material expressed by these clones will be described elsewhere (E. De Maeyer, manuscript in preparation).

Design of the synthetic gene

Initially, the published DNA sequence⁷ coding for mature human IFN-α, was scanned with a computer program designed to detect both complementary and repeated sequences (D. J. Gilman, unpublished results). A number of such sequences were identified. For example, bases 75-85 in the native sequence, d(TCCTTCCTCCT), are complementary to bases 487-497, d(AGGAGGAAGGA), and bases 32-40, d(ACAGGAGGA) are complementary to bases 79-87, d(TCCTCCTGT). Similarly, there are 4 separate complementary pairs of octamers and 13 complementary pairs of heptamers. The sequence d(GAAGAAATAC) (bases 359-368) is repeated (bases 399-408). There are seven separate repeated heptamers, five repeated octamers and one repeated nonamer. Numbering here is with respect to the first base in the triplet coding for Nterminal cysteine (T=1) in the mature peptide (see Fig. 3 in ref. 7).

We reasoned that elimination of these features as far as possible within the constraints of the genetic code would make correct ligation of synthetic oligonucleotides more straightforward. The target sequence is illustrated in Fig. 1. Dots above bases in the coding strand indicate changes with respect to the native sequence (71 in total). By so modifying the natural sequence, the longest self-complementary regions are four heptamers, all separated by more than 100 bp. There are two repeated nonanucleotides; d(AATCTTCAA) in blocks 28 and 64/66 and d(AAAAAGTAT) in blocks 50 and 56. There are three repeated heptamers and one repeated octamer.

The gene was divided (Fig. 1) into a series of oligonucleotides of ~ 15 residues so as to give overlaps of at least 7 bp on each side of all ligation points. It is convenient to use oligonucleotides of this size as the synthesis and purification of significantly larger molecules may not always be straightforward³³. Where possible, changes in the native sequence are such as to introduce codons which may be preferred for high levels of expression in bacteria^{35–37}. The codon usage profile is compared with that of the native strand in Table 1.

Outline of chemical synthesis strategies

The basic chemistry involved in our synthetic approach is summarized at the top of Fig. 2 and in its legend and we have previously described the methodology in some detail^{33,34}. During this study several minor changes have been made which considerably improve both the rate and yields of synthesis. In our hands, use of mesitylenesulphonyl-3-nitro-1,2,4-triazole³⁸ as condensing agent increases yields in dimer coupling reactions and allows individual reaction times to be reduced to ~1 h. We have also reduced the deprotection/washing cycle to ~ 0.5 h so that the overall time for addition of each dimer block to a growing chain is ~1.5 h. With a semi-automated solvent delivery system it is convenient to perform two or three such assemblies concurrently so that up to two pentadecanucleotides can be constructed per man-day. Previously we have not attempted to dry the support between coupling cycles but co-evaporation of the polydimethylacrylamide resin with anhydrous pyridine before each condensation reaction again significantly improves the final yields of purified deprotected oligonucleotides. Thus (Fig. 2a, c), in the syntheses of blocks 24 and 65 (Fig. 1) the desired oligonucleotide product is the major peak in ion-exchange HPLC on Partisil 10-SAX.

Further resolution by reverse-phase HPLC on μ -Bondapak C_{18} columns (Fig. 2b, d) gives pure material in most cases, as judged by standard 5'-[32 P]-phosphorylation and sizing on 20% polyacrylamide gels in 7 M urea (for examples see Fig. 2e, f) 39 . In our previous work 33,34 , oligonucleotides synthesized by this approach were characterized by complete sequencing. During this synthesis, the oligonucleotides were characterized by sizing

(above) and 5' residues were confirmed after total snake venom phosphodiesterase digestion of 5'-[³²P]-labelled aliquots. In cases where unequivocal identification of product by HPLC and sizing was not possible, complete sequencing was undertaken.

A more complete description of improved methodology for the synthesis of these oligonucleotides will be published elsewhere. The oligomers 5, 7, 17, 44, 58 and 63 could not be purified by standard Partisil 10-SAX ion-exchange HPLC with phosphate gradients in a 5% ethamol system at ambient temperature. Elevated temperature and increased ethanol concentration or electrophoretic techniques were necessary³³. We note that all these oligomers contain three or more consecutive dG residues. In retrospect, these features could have been avoided in oligomers 5, 7, 17, 44 and 63 by alternative choices of codons but it is obviously desirable to be able to synthesize such molecules so as to have the widest possible latitude in codon usage. Furthermore, this sequence cannot be avoided in oligomer 58 given the amino acid sequence Trp-Glu [d(TGGGAPur.)].

Ligation strategy

Eleven groups of oligomers (A-K) were initially ligated separately (Fig. 3a). 5' Phosphorylation with low specific activity ³²P-ATP and polynucleotide kinase was performed on

individual oligomers which were then isolated by elution from 20% polyacrylamide gels in 7 M urea (oligomers 1 and 67 were not phosphorylated at this stage). After denaturation, slow annealing and ligation, reaction mixtures were examined on polyacrylamide gels in both native and denaturing conditions (Fig. 3b, c). Ligated products of the expected size were isolated by preparative polyacrylamide gel electrophoresis in non-denaturing conditions, elution and ethanol precipitation. Product recovery was estimated by counting aliquots dried separately on GFC filter disks. Aliquots of the 11 fragments were combined, annealed and again ligated with T4-induced DNA ligase to give the four blocks shown in Fig. 3d. Ligation of these four blocks in a similar manner gave a discrete band of approximately the expected size as identified by 3.5% polyacrylamide native electrophoresis with appropriately sized markers (Fig. 3e). This fragment was isolated either by excision and elution from the gel or by gel permeation chromatography of the reaction mixture. 5' Ends were phosphorylated by standard techniques for plasmid insertion.

Construction of recombinant plasmids

The synthetic gene contains single-stranded cohesive ends to facilitate ligation to a *BamHI-SalI* plasmid vector. The plasmid, pPM50, chosen for cloning the synthetic gene, is a derivative of plasmid pAT153 (ref. 40) in which the region of the tetracycline

oligonucleotide was cleaved from the solid phase (40 mg of oligomersubstituted resin) and all protecting groups were removed (procedure B, ref. 34) by sequentially reacting with 0.3 M 1,1,4,4-tetramethyl-guanidinium 4-nitrobenzaldoximate¹⁸ in dioxan/water (1/1, 2 ml) at room temperature for 60 h; concentrated ammonia at 50 °C for 5 h; 80% aqueous acetic acid for 30 min at room temperature. The deprotected oligomer was dissolved in pyridine (0.05 ml), ethanol/water (3/7, 2-4 ml) and suitable aliquots were purified initially by HPLC on Partisil 10-SAX (examples in 2a and c). Columns were eluted at a flow rate of 2 ml min⁻¹ with a gradient from 1 mM to 0.4 M potassium phosphate, pH 6.8 in 5% ethanol or pH 6.5 in 30% ethanol, over a period of 50 min at ambient temperature. The most retained peak(s) were collected, evaporated, redissolved in water (5 ml) and applied to a μ -Bondapak C₁₈ reverse-phase column. The oligonucleotide was further purified by first eluting with 0.1 M ammonium acetate, then with a gradient of 10-25%~0.1~M ammonium acetate/acetonitrile (1/1) over 40~min with a flow rate of 2 ml min⁻¹ at ambient temperature (examples in b and d). After addition of excess triethylamine, oligonucleotide-containing fractions were lyophilized and redissolved in water (1 ml). Aliquots of each solution (80 pmol of oligonucleotide) were evaporated and phosphorylated with 1.1 units of T4-induced polynucleotide kinase in 10 μ l of a solution containing 160 pmol [γ -32P]ATP (12.5 Ci mmol⁻¹), 0.1 mM spermidine, 20 mM dithiothreitol (DTT), 10 mM MgCl₂, 50 mM Tris-HCl (pH 9.0) and 0.1 mM EDTA for 45 min at 37 °C. Reactions were terminated by addition of 270 µl of 50 mM Tris-borate (pH 8.3), 1 mM EDTA in 80% formamide and heating to 90 °C for 5 min. A 7-µl aliquot was examined on a 20% polyacrylamide gel in 7 M urea (examples in e and f).

Synthetic Interferon Gene

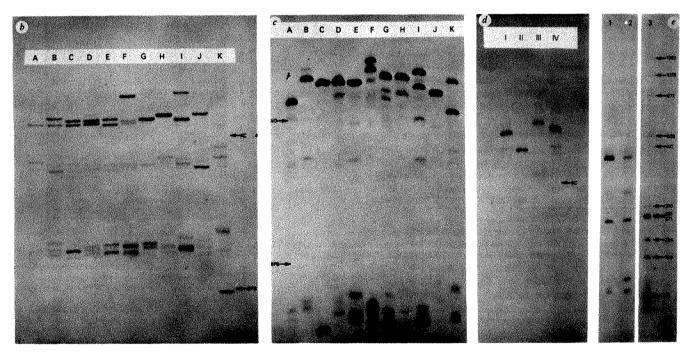

Fig. 3 Ligation of chemically synthesized oligonucleotides. a, Ligation strategy. Aliquots of the chemically synthesized oligonucleotides, 2-66 (40 pmol of each), were phosphorylated with 6.5 units of T4-induced polynucleotide kinase in 25 μl of a solution containing 80 pmol [γ-²²P]ATP (8.5 Ci mmol⁻¹), 100 μM spermidine, 20 mM DTT, 10 mM MgCl₂, 50 mM Tris-HCl (ρH 9.0) and 0.1 mM EDTA for 30 min at 37 °C. Each oligonucleotide was ethanol precipitated and fractionated by electrophoresis on a 20% polyacrylamide gel in 7 M urea. The ²²P-labelled oligomers were sliced from the gel and eluted⁴⁶. Eleven separate T4 ligase-catalysed joining reactions were performed to give fragments A to K. In groups A and K, oligonucleotides 1 and 67, respectively, were not phosphorylated. For the construction of each fragment, the terminal oligonucleotides were present in excess over the internal oligonucleotides. For example, fragment B was constructed by annealing, in 50 μl water, 3.8 pmol of oligonucleotides 7 and 12, 3.6 pmol of 8 and 11 and 3.4 pmol of 9 and 10, heating to 100 °C and cooling slowly to room temperature. Each mixture was dried in vacuo and ligated in 20 μl of a solution containing T4 DNA ligase (26 units), 74 mM Tris-HCl (ρH 7.6), 6.6 mM MgCl₂, 10 mM DTT, 2.9 mM ATP, 1.6 mM mercaptoethanol and 1.6 μg bovine serum albumin for 24 h at 22 °C. b, Aliquots (1%) of the reaction mixtures were examined on a 15% polyacrylamide gel in 7 M urea. c, The DNA from each of the remaining mixtures was ethanol precipitated and fractionated on a 15% polyacrylamide gel in the absence of urea. The DNA from each band was eluted from the gel. An aliquot of each band was re-run in denaturing conditions. In each group, the most slowly migrating band had oligonucleotide strands of the correct size. d, Fragments I-IV were constructed from 0.1-pmol of fragments A-K. Amealing was carried out at 45 °C and the mixtures were ligated as described previously. The fragments were isolated by electrophoresis on a 10% polyacrylamide gel i

resistance determinant between the EcoRI and BamHI sites has been replaced by a 95-bp AluI-generated fragment from the promoter region of the E. coli lactose operon. The construction of this plasmid, as shown in Fig. 4A, was arranged so that insertion of the AluI fragment resulted in the regeneration of both the EcoRI and BamHI recognition sequences. Intro-

duction of the synthetic oligonucleotide between the BamHI and SalI cleavage sites of the pPM50 vector plasmid should therefore place the interferon coding sequence under the transcriptional control of the lac promoter in an orientation such that the ATG codon forms a 'hybrid ribosome binding site' with the lac promoter Shine-Dalgarno (S-D) sequence⁴¹. Thus, the

sequence around the BamHI site will be

S-D Bam HI Met Cys 5'----AGGAAACAGGATCCATGTGT----3'

A construction of this type should achieve active transcription and translation leading to expression of the interferon coding sequence. Such promoter fragments containing an EcoRI cleavage site in place of the BamHI site have been used to promote expression of the streptomycin resistance gene of the plasmid R300B (P.M., unpublished data). Similarly, plasmid vectors incorporating the analogous AluI fragment from a mutant lac promoter (UV5) have been used to promote high level expression of various heterologous genes (see, for instance, refs. 42-44).

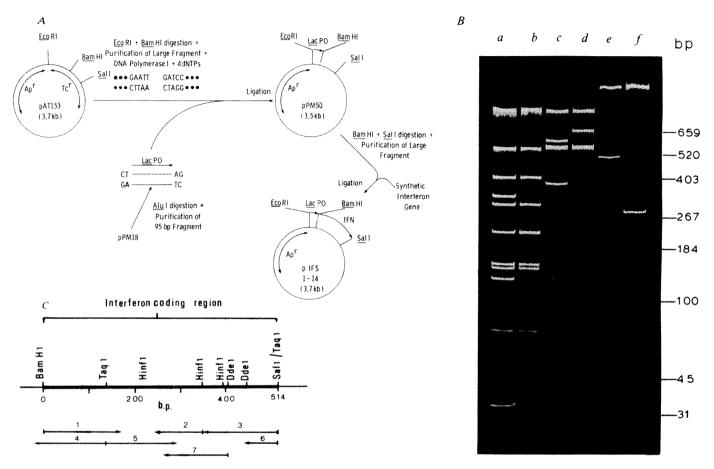

Fig. 4 A, Construction of the recombinant pIFS plasmids. DNA (7 μg) of the parental plasmid, pAT153 (ref. 40), was digested sequentially for 60 min at 37 °C with restriction endonucleases *Eco*RI and *Bam*HI in 10 mM Tris-HCl (pH 7.6), 6 mM MgCl₂ and 1 mM DTT containing 50 mM (*Eco*RI) or 150 mM (*Bam*HI) NaCl. Reactions were terminated by extraction with phenol/chloroform (3/1) and ethanol precipitation. The DNA was resuspended in 30 µl DNA polymerase I buffer (6 mM Tris-HCl (pH 7.4), 7 mM MgCl₂, 1 mM DTT) containing 40 µM each of dATP, dGTP, dCTP and dTTP to synthesize 3'-oligonucleotide extensions complementary to the protruding 5'-oligonucleotide ends generated by the endonuclease treatment. The reaction was initiated by addition of DNA polymerase I-Klenow fragment (1.5 units) and incubated at 11 °C for 90 min. 3 H-dTTP (3 μ Ci; 16 Ci mmol $^{-1}$) was added so as to follow the extent of reaction by trichloroacetic acid precipitation of 5-µl samples. The reaction was terminated by extraction with phenol/chloroform (3/1) and ethanol precipitation. Plasmid pPMR is a derivative of the vector plasmid pACYC184 (ref. 49) which has a 6.6-kb EcoRI fragment derived from \(\rho\)plac5(ref. 50) inserted at the EcoRI site in the plasmid chloramphenical resistance gene. The λplac5 fragment carries the promoter region of the E. coli lactose operon and part of the β-galactosidase gene⁵¹. Plasmid pPM18 DNA (15 μg) was digested with restriction endonuclease AluI in 6 mM Tris-HCI (PH 7.6), 6 mM MgCl₂, 50 mM NaCl, 6 mM β -mercaptoethanol and the 95-bp fragment containing the E. coli lactose operon promoter/operator region isolated by electroelution³² from a 5% polyacrylamide gel⁵³ and purified by chromatography on DE52 DEAE-cellulose⁵². The 'filled in' *EcoRI/BamHI* cleaved pAT153 DNA was blunt-end ligated to the 95-bp *AluI* fragment in a volume of 50 µl in 20 mM Tris-HCl (pH 7.6), 10 mM MgCl₂, 10 mM DTT, 5 mM ATP, with T4 DNA ligase (5 units) at 10 °C for 16 h. The ligated mixture was transformed to *E. coli* strain C600 (ref. 54) and ampicillin-resistant transformant colonies selected on antibiotic (25 µg ml⁻¹) minimal X-gal (20 µg ml⁻¹) medium⁵⁵. Colonies containing recombinant plasmids with the *lac* promoter/operator sequence were identified by their blue coloration on the X-gal medium, due to constitutive expression of the chromosomal \(\beta\)-galactosidase gene. Plasmid DNA, isolated from eight independent blue colony transformants, was screened by digestion with restriction endonucleases EcoRI and BamHI and one found to contain a single cleavage site for each enzyme separated by ~100 bp. Nucleotide sequence determination of the small (100 bp) fragment generated by digestion with these two enzymes showed that it contained the lac promoter/operator sequence flanked by EcoRI and BamHI sites and orientated such that transcription would proceed towards the BamHI site (P.M., unpublished data). This plasmid was named pPM50 and was used for the subsequent cloning of the synthetic interferon gene. DNA (4 µg) of plasmid pPM50 was digested with restriction endonucleases *Bam*H1 and *Sal*1 in 10 mM Tris-HCl (pH 7.6), 6 mM MgCl₂, 150 mM NaCl and 1 mM DTT at 37 °C for 60 min. The reaction was terminated by extraction with phenol/chloroform and the products subjected to electrophoresis through 1% agarose in 40 mM Tris-HCl (pH 7.8), 6 mM sodium acetate, 1 mM EDTA buffer. The larger 3.2-kb fragment was isolated and chromatography on DE52 DEAE-cellulose. The purified BamHI-Sal1 3.2-kb vector fragment (1 µg) was ligated to the synthetic oligonucleotide preparation with T4 DNA ligase (0.4 units) in a total reaction volume of 30 µl containing 20 mM Tris-HCl (pH 7.6), 10 mM MgCl₂, 10 mM DTT at 12.5 °C for 16 h. The reaction mixture was used to transform competent cells of E. coli K-12, strain MRC 8 (F⁻, dap 103, hsd R, met B1, glm 533, upp 1, dap 101, sup E, rec A) and ampicillin-resistance transformants selected on L-agar⁵⁵ medium containing N-acetylglucosamine (0.02%) and diaminopimelic acid (50 µg ml⁻¹). Transformant colonies containing recombinant plasmids which carried the synthetic oligonucleotide (pIFS plasmids) were identified by Grunstein-Hogness⁴⁵ colony hybridization using a radioactively ³²P-labelled oligonucleotide from within the synthetic sequence (coding for amino acids 78-97) as hybridization probe. B, Structure of plasmids containing the synthetic oligonucleotide. Restriction endonuclease-digested plasmid DNAs were analysed by electrophoresis through 6% HinfI digests of pIFS 1 (a) and pPM50 (b); TaqI digests of pIFS 1 (c) and pPM50 (d); BamHI and SalI double digests of pIFS 1 (e) and pPM50 (f). Reaction conditions were as suggested by the enzyme suppliers. C, Strategy for sequence determination of the synthetic interferon gene. Top line shows the positions of relevant restriction endonuclease cleavage sites within the synthetic oligonucleotide insert (heavy line) of the recombinant plasmid pIFS1. The nucleotide sequence was determined by use of the Maxam-Gilbert method⁴⁶ on fragments labelled at the 3' end by use of DNA polymerase I (Klenow) with an appropriate $[\alpha^{-32}P]$ -labelled deoxynucleoside triphosphate. The arrows (1-7) indicate the direction and extent of the sequence determined from each labelling position. Fragments sequenced are as follows (the numbers refer to the arrows and the labelled ends of the restriction fragments are designated by an asterisk); 1, BamHI-Sall; 2, HinfI-HinfI*; 3, BamHI-SalI*; 4, EcoRI-TaqI*; 5, *TaqI-DdeI; 6, DdeI-TaqI*; 7, TaqI-DdeI*

Recombinant plasmids of this type were constructed by ligation of purified BamHI-SalI-cut pPM50 vector DNA to the synthetic oligonucleotide preparation. Two cloning experiments were performed. In one case, plasmid DNA was ligated to a gel-purified 514-bp product of the oligonucleotide ligation mix; in the other, plasmid DNA was mixed with the total oligonucleotide ligation mix and ligation allowed to continue. The ligation mixtures were used for transformation of E. coli strain MRC8 and the resulting ampicillin-resistant transformant colonies screened for the presence of the synthetic oligonucleotide insert by Grunstein-Hogness colony hybridization⁴⁵ using as hybridization probe a radioactively labelled synthetic oligonucleotide, 60 residues long, coding for amino acids 78-97 of the interferon sequence. Two positively responding colonies were detected among the transformants arising from the ligation of the vector plasmid to the purified 514-bp fragment, and a further 12 from the other ligation. This corresponded to a 10% yield of recombinant plasmid transformants.

Analysis of the plasmid DNA isolated from these colonies showed that all 14 contained equivalent-size plasmids (pIFS 1-14). On digestion with BamHI and SalI endonucleases and examination of the products by gel electrophoresis, all these plasmid DNAs produced an identical 514-bp fragment in addition to the 3.2-kilobase (kb) vector fragment. Four of these plasmids were selected for more detailed analysis (pIFS 1, 2, 4,

Inspection of the theoretical nucleotide sequence of the 514bp synthetic oligonucleotide (Fig. 1) showed that the d(TCGA) sequence, which is cut by endonuclease TaqI, is present twice (at amino acid residues 43/44 and at the SalI restriction site) and the d(GANTC) sequence which is cut by the endonuclease HinfI is present three times (at amino acid residues 72/73, 115/116 and 126/127). Therefore, cleavage of this sequence by these endonucleases should yield an internal 375-bp fragment in the case of TaqI and 129-bp and 34-bp internal fragments in the case of Hinfl. Examination by acrylamide gel electrophoresis of the DNA fragments produced on treatment of the four selected pIFS plasmid DNAs with these two endonucleases showed that all produced these predicted fragments, whereas the vector plasmid pPM50 produced no such fragments. Figure 4B shows these digestion patterns for one of the recombinant plasmids, pIFS 1. We therefore conclude that these four pIFS plasmids must contain a 514-bp insert between the BamHI and SalI cleavage sites which has several widely spaced restriction endonuclease recognition sequences in the positions predicted from the theoretical sequence of the interferon gene oligonucleotide. To confirm that the correct interferon gene sequence was present in these clones, the 514-bp BamHI-SalI fragment from one plasmid, pIFS 1, was subjected to complete nucleotide sequence determination⁴⁶ on terminally ³²P-labelled DNA fragments according to the strategy shown in Fig. 4C. The nucleotide sequence so determined is in complete agreement with the theoretical sequence shown in Fig. 1.

Discussion

The rapid synthesis of genes of this size should allow several interesting problems to be examined. There has been some speculation about the mechanisms by which the expression of human genes cloned into bacteria is controlled (see discussion in ref. 47). Obviously, regulation at the level of transcription or translation initiation will be of fundamental importance and a number of elegant promoter systems have been devised. These have allowed high levels of 'eukaryotic' protein synthesis to be achieved, presumably as a result of the presence of abundant copies of their mRNAs. However, studies by Grantham et al. 35-37 comparing the mRNA sequences of highly expressed and weakly expressed genes in bacteria suggest that highly expressed genes have a special strategy for the selection of codons, particulary at position III. This may reflect an optimization of codon-anticodon pairing energies. We have attempted to reproduce this pattern of codon usage in the synthetic gene (Table 1). Others⁸ have noted the rarity of the dinucleotide CG

in human IFN mRNA, which reflects the strong preference for AGA and AGG as codons for arginine. Whereas the native sequence contains 3 CG residues, 2 of which occur within codons, the synthetic sequence contains 22 CG residues, 14 of which occur within codons. The synthetic sequence also has a marked increase in the incidence of CUG for leucine and of CCG for proline. Insertion of either the natural human DNA sequence or the sequence described herein (or further variations) into the same vector and comparison of expression levels may shed some light on these questions. Examination of, for example, the effect of using a particular codon twice when the same amino acid occurs consecutively in the protein awaits synthesis of further gene variants (see below). It would also be of interest to determine whether any of the complementary sequences within the natural gene (or within the synthetic gene) affects expression. This could involve either formation of internal DNA cruciform structures 48 with resultant influence on transcription or formation of secondary structures at the mRNA level with a resultant influence on translation.

An exciting recent development concerning interferon has been the construction of hybrid genes. Cleavage at a convenient common BglII site within the coding sequences of a number of the IFN- α genes^{23,24} allows fusion of the N-terminal sequence from one gene with the C-terminal sequence from another. Thus, in addition to the range of natural IFN- α molecules with their different pharmacological profiles¹¹, a potentially large number of hybrid interferons with further distinct properties are accessible. The availability of a large pool of synthetic fragments clearly extends the range of interferon analogues which can be prepared. It should be possible to compare rapidly the relative activities of proteins generated by this approach in a common vector system and it will be interesting to determine whether the natural interferons can be improved upon. The wider implication is that classical medicinal chemistry structure-activity analysis should be possible in relatively large peptides. This may yield considerable benefits in a number of important pharmaceutical areas.

We thank Dr T. F. W. McKillop for helpful discussions and for his continuous support, Drs E. C. Dart, J. S. Morley, W. J. Brammar, J. D. Windass and K. Atherton for their interest and support, Dr D. J. Gilman for computer analyses, and Dr S. Brenner for E. coli K-12.

Regular patchy distribution of cytochrome oxidase staining in primary visual cortex of macaque monkey

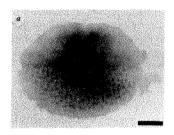

Jonathan C. Horton & David H. Hubel

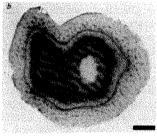

Department of Neurobiology, Harvard Medical School, 25 Shattuck Street, Boston, Massachusetts 02115, USA

In two preliminary studies, normal macaque¹ and squirrel-monkey^{2,3} striate cortex cut parallel to the surface and stained for cytochrome oxidase (a mitochondrial enzyme) showed a striking pattern of regularly spaced patches. This was surprising. since until then no physiological or anatomical studies had suggested such a patchy organization. In the present study in the macaque we found that the patches were arranged in rows spaced about 350 µm apart. When one eye was injected with tritiated proline the rows of patches in layers II and III lay in register with the ocular-dominance bands seen autoradiographically in layer IVc. Removing one eye caused the patches in every other row to shrink and blanch. The rows of patches are therefore centred on the ocular dominance columns. Regions labelled by 2-deoxyglucose autoradiography after stimulating one eve with black-and-white stripes in all orientations consisted of rows of patches that lay in register with the cytochrome oxidase patches in every other row. On stimulating monkeys with stripes of a single orientation, the deoxyglucose-labelled regions formed a lattice that included the cytochrome oxidase patches but was more extensive. Thus either the deoxyglucose is not labelling the orientation columns at all, or the orientation columns coalesce in the areas marked by the cytochrome oxidase stain.

Wong-Riley has used a stain for cytochrome oxidase to demonstrate a pattern of alternating light and dark bands in layer IV of a monocularly deprived kitten, the lighter bands presumably reflecting a lowered metabolic activity in the set of columns belonging to the closed eye4. Our original purpose was to examine cytochrome oxidase activity in the different layers of the striate cortex of the normal macaque monkey. Sections (50 μm) from glutaraldehyde-paraformaldehyde fixed tissue were cut on a freezing microtome and processed for cytochrome oxidase activity following a procedure modified from Seligman et al.5. In sections cut perpendicular to the cortical surface, cytochrome oxidase staining was darkest in layers IVa and IVc, which receive the major direct projections from the lateral geniculate body⁶. Layers II and III were lightly stained but showed periodic fluctuations in density. To examine the pattern more closely we sectioned the cortex tangentially. Cytochrome oxidase staining showed an array of dark oval patches about 150 × 200 µm which were most obvious in Layers II and III but were also present, though faint, in layer VI. Although varying to some extent from animal to animal, the patches were generally aligned in rows spaced $\sim 350 \,\mu m$ apart, with the long axis of the patches parallel to the rows. Within a row the patches were ~550 µm apart, but in some places became confluent. Occasionally, patches in neighbouring rows seemed to be aligned, forming a square or hexagonal array over small regions of cortex.

The rows of cytochrome oxidase patches resembled ocular dominance columns in their spacing and in intersecting the 17-18 border at right angles (Fig 1a). It was obviously important to learn whether these rows were really related to the ocular dominance columns, and, if so, whether the patches lay along the dominance columns or straddled the borders between them. We therefore removed one eye of a macaque monkey, killed the animal 10 days later and stained the visual cortex for cytochrome oxidase. Sections through layer IVc showed ocular dominance columns visable as alternating light and dark bands (Fig. 1b), in striking contrast to the uniformly deep staining of this layer for cytochrome oxidase in normal monkeys. In sections passing through layers II and III there were parallel

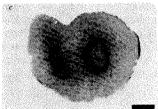

Fig. 1 a, Tangential section through the superficial layers of the visual cortex of the normal macaque monkey; cytochrome oxidase stain. The section passes through the 17-18 border, which runs horizontally in the figure with area 17 below and 18 above. The patches in 17 are aligned in rows perpendicular to the 17-18 border. b, Cytochrome oxidase section tangential to area 17 in a macaque monkey that had its right eye removed 10 days previously. Section grazes layer V, which forms a pale oval near the centre, surrounded from within out by layers IVc (dark stripes), IVb (pale and narrow), IVa (dark, very narrow) and II, III (containing patches). Dark and pale alternating stripes in layer IVc are typical of ocular dominance columns, in their regularity, direction and spacing. c, Same monkey as in b. This section is more superficial, grazing layer IVb. Cytochrome oxidase patches lie in rows that are alternately dark and pale: the pale rows lie over the light stripes in layer IVc corresponding to the injured eye. Scale bar, 2 mm.

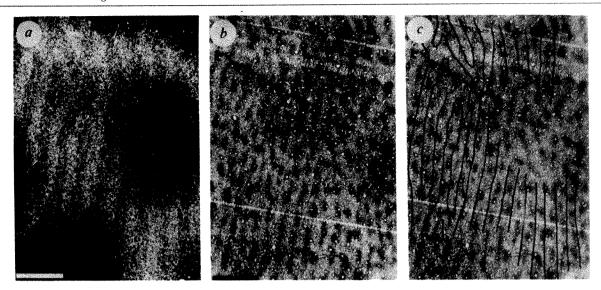

Fig. 2 a, Dark-field autoradiograph of striate cortex in a normal monkey whose right eye was injected with ³H-proline 2 weeks earlier. The section is tangential, grazing layer V (dark ovals) but passing mainly through layer IVc. Here typical ocular dominance columns are seen as light bands of label corresponding to the injected eye separated by darker gaps. b, More superficial section from the same block as a, cytochrome oxidase stain. The rows of cytochrome oxidase patches in the superficial layers follow the pattern of the ocular dominance patches. This is shown in c by drawing the borders of the columns from a directly onto b. Scale bar, 1 mm.

rows of patches as in normal monkeys, but in every other row the patches were paler and smaller (Fig. 1c). When one of these sections was aligned with a section through layer IVc, using as a guide small blood vessels (which generally run normal to the cortex through its full thickness), the alternating rows of dark and light patches fell into precise register with the dark and light bands in layer IVc. This indicated that the rows of patches in normal monkeys lie centred on the ocular dominance columns rather than along the borders separating them. All the cells in any given patch are thus likely to be strongly dominated by the same eye.

In a second monkey we injected one eye with 2 mCi 3 H-proline to label the ocular dominance columns in layer IVc by transneuronal autoradiography. Figure 2a, a dark-field autoradiograph of a section tangential to layer IVc, shows typical ocular dominance columns in which the light bands represent the injected eye. A more superficial section stained for cytochrome oxidase shows the expected array of patches (Fig. 2b). When aligned with the autoradiograph, again using radial blood vessels as a guide, the rows of patches follow the course of the ocular dominance columns and are centred on them (Fig. 2c).

In a third monkey we used the 2-deoxyglucose method to label regions of cortex activated by stimulation of one eye. We anaesthetized the animal with sodium thiopental injected 14C-2deoxyglucose (100 µCi per kg), and stimulated the visual field of the right eye with a set of black-and-white stripes of irregular width and spacing, moved slowly back and forth and steadily rotated so as to expose the animal to all orientations about once every minute. After 45 min the monkey was killed, the brain perfused, frozen and sectioned and the dried sections pressed against X-ray film. Alternate sections were stained for cytochrome oxidase. A pattern representing ocular dominance columns was visible in the deoxyglucose autoradiographs of tangential sections through layer IVc. An adjacent section stained for cytochrome oxidase showed no trace of ocular dominance columns in layer IVc, indicating that the brief period of monocular stimulation was insufficient to affect cytochrome oxidase levels. When a cytochrome oxidase section through layers II and III (Fig. 3a) was superimposed on a deoxyglucose autoradiographs of layer IVc, the rows of cytochrome oxidase patches were again centred over the ocular dominance columns, confirming the results of the eye removal and transneuronal autoradiography experiments.

Deoxyglucose sections adjacent to Fig. 3a showed an array of patches of increased deoxyglucose uptake (Fig. 3b) which lay

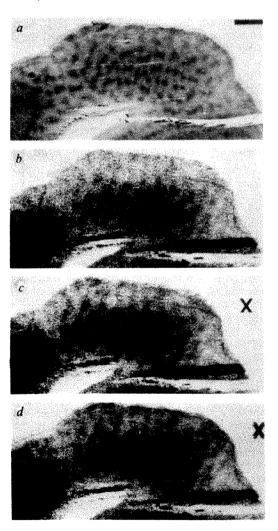

Fig. 3 a, An array of cytochrome oxidase patches in layers II, III of striate cortex of a normal macaque monkey. b, This 2-deoxyglucose autoradiograph of an adjacent section shows patches of uptake of label after stimulation of one eye with black-and-white stripes in all orientations. c, When a and b, photographed on film, are overlapped in precise register the two patterns reinforce. d. When shifted out of alignment by 150 μm (see Xs) the patterns tend to cancel. Scale bar, 1 mm.

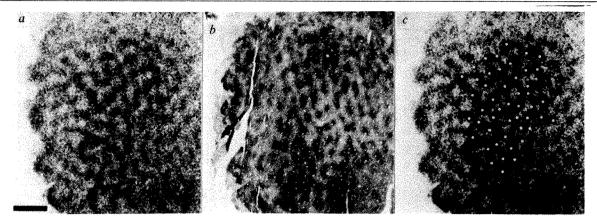

Fig. 4 a, Complex pattern of ¹⁴C-2-deoxyglucose label in layers II, III of macaque striate cortex after stimulation of both eyes with vertical stripes. b, An adjacent section stained for cytochrome oxidase shows an array of patches. c, The cytochrome oxidase patches fall within the lattice of deoxyglucose label, as shown by representing each patch in b, with a small white dot, and placing them directly on a. Scale bar, 1 mm.

over the deoxyglucose-labelled ocular dominance columns in layer IVc. A similar patchy pattern from stimulating one eye with all orientations has been observed by Kennedy et al. and by Hendrickson and Wilson⁸. The deoxyglucose pattern resembled the cytochrome oxidase pattern, but the patches were larger and the rows more widely spaced. When Figs 3a and 3b were superimposed, in and out of register (Fig. 3c, d), the patches of increased deoxyglucose label matched the cytochrome patches lying in every other row.

Attempts to learn whether there was any relationship between the cytochrome exidase patches and orientation columns produced unexpected results. In two experiments we stimulated with vertical black-and-white stripes after injecting 2-deoxyglucose. As shown in Fig 4a, the pattern in tangential sections through layers II and III was periodic and yet highly complex, forming a lattice of stripes, rosettes and patches, as reported previously9. The patches seen in adjacent sections stained for cytochrome oxidase (Fig. 4b) fell along the lattice of deoxyglucose label (Fig. 4c). Where the deoxyglucose pattern appeared patchy, the patches tended to coincide with the cytochrome oxidase patches; the deoxyglucose pattern thus included the cytochrome patches but seemed to extend beyond and between them. We first thought that the cytochrome oxidase patches might have some special relationship to vertical orientation columns², but two similar experiments using deoxyglucose and horizontal stripes gave the same result, with the cytochrome oxidase patches lying along the lattice formed by the deoxyglucose label. Thus all orientations of line stimuli probably activate cortex in the regions of the patches, as indeed is suggested by the deoxyglucose experiment in which one eye was stimulated with all orientations. A combination of physiological recordings and a double-label deoxyglucose technique 10 will probably help clarify the relationship between the patches and the orientation columns.

In squirrel monkeys Humphrey and Hendrickson³ have shown that the deoxyglucose pattern obtained when both eyes are stimulated with all orientations is identical to the cytochrome oxidase pattern. Similarly, we have found in two squirrel monkeys a strong correlation between the cytochrome oxidase patches and the pattern after stimulation with horizontal stripes in both eyes. In the human and the galago, a prosimian primate, the striate cortex likewise shows cytochrome oxidase patches, we find that the cat and tree shrew lack such patches. A patchy distribution of cytochrome oxidase staining may reflect a system of inputs, outputs and intrinsic connections unique to the visual cortex of primates.

We thank Birthe Storal, Suzanne Fenstemaker and Debra Hamburger for technical help, Marc Peloquin for photography, Olivia Brum for typing the manuscript, and Helen Sherk, Simon LeVay and Torsten Wiesel for advice and criticism. This study was funded by NIH grant EY 00605; J.C.H. is supported by Medical Scientist Training Program grant GM 02220.

Effect of chemical environment on levels of substance P and somatostatin in cultured sensory neurones

Anne W. Mudge*

Departments of Physiology and Pharmacology, Harvard Medical School, 25 Shattuck Street, Boston, Massachusetts 02115, USA

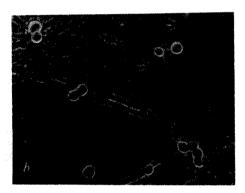

The neurotransmitter produced by autonomic neurones is influenced by the environment in which they develop1. For example, Le Douarin² and her colleagues have shown that regions of the neural crest which normally give rise to cholinergic ganglia can be induced to develop into adrenergic cells by transplanting them into a region of the crest which normally gives rise to adrenergic ganglia. Similarly, sympathetic neurones grown in culture express either adrenergic or cholinergic properties depending on whether they are grown in the absence or presence of certain types of non-neuronal cells 1,3-5. Patterson et al.6.7 demonstrated that this is not due to selective survival of a population of neurones but that the transmitter choice of individual neurones can be altered by soluble factors produced by non-neuronal cells. Like autonomic neurones, sensory neurones derive from the neural crest and it therefore seems likely that the type of transmitter they produce could also be influenced by the environment in which they develop. Here I demonstrate that when sensory neurones from embryonic chick dorsal root ganglia are grown together with ganglionic nonneuronal cells or with medium 'conditioned' by incubation with such cells, they produce increased amounts of somatostatin (SOM). This increase is neither accompanied by an increase in substance P (SP) content nor a detectable change in neuronal survival and thus differs from the effect of nerve growth factor (NGF), which increases survival of sensory neurones without affecting the relative levels of SOM and SP.

^{*} Present address: MRC Neuroimmunology Project, Department of Zoology, University College London, Gower Street, London WC1E 6BT, UK.

Although the transmitters used by sensory neurones are unknown, several peptides, namely substance P, somatostatin, cholecystokinin (CCK) and vasoactive intestinal peptide (VIP), are present in small-diameter neurones of the DRG (dorsal root ganglia) and in small-diameter fibres that project into the spinal cord dorsal horn⁸. Although SP and SOM seem to be in separate populations of neurones⁹, it is not known which subclasses of small fibres contain these peptides or whether they coexist with other transmitters. As both SP and SOM can be released from sensory neurones¹⁰⁻¹³ and both can alter neuronal firing rates in the dorsal horn^{14,15}, it seems likely that they (and probably also CCK and VIP¹⁶) are involved in synaptic transmission in the spinal cord, although their functions remain unclear.

DRG from 10-day-old chicken embryos were dissociated to single cells and plated on to collagen-coated tissue culture dishes

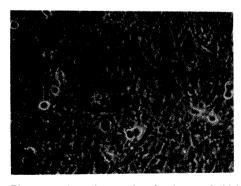

Fig. 1 Phase contrast micrographs of cultures of chick DRG. Dissociated cells were plated on to collagen-coated 35-mm culture dishes (Falcon). The growth medium used was Eagle's minimum essential medium (MEM) supplemented with 2 mM glutamine, 50 μg ml⁻¹ penicillin, 50 U ml⁻¹ streptomycin, 10% horse serum (all Gibco), 5% chick embryo extract (CEE) plus nerve growth factor (NGF). a, Neurones plus ganglionic non-neuronal cells 24 h after plating. b, Neurones plus ganglionic non-neuronal cells 15 days after plating. The dividing non-neuronal cells were confluent 6 days after plating, at which time the cultures were irradiated with ^oCo to arrest further cell division. c, Neurones-alone cultures 15 days after plating. These cultures were treated with $5 \times 10^{-6} \,\mathrm{M}$ cytosine arabinoside for the period between 12 h and 5 days after plating to kill almost all the non-neuronal cells. Cultures from the same plating as in a, b and c provided the data shown in Fig. 2. Scale bar, 50 µm

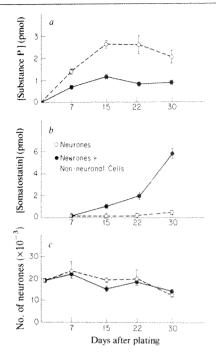

Fig. 2 SP (a) and SOM (b) content of DRG cultures grown for the number of days indicated in either the presence (\bullet) or virtual absence (\bigcirc) of ganglionic non-neuronal cells. The number of neurones present in each culture is shown in c. Data are expressed as mean \pm s.e.m. of either three or four cultures; all cultures were from the same plating.

to give two types of culture: (1) cultures of 'neurones alone' in which almost all the non-neuronal cells were eliminated by treatment with cytosine arabinoside; (2) neurones grown together with dividing ganglionic non-neuronal cells. Within 24 h after plating, both neurones and non-neuronal cells had attached to the collagen substratum and phase-bright, neurone-like cells had extended processes (Fig. 1a) which grew during the next 2 weeks to form a dense network (Fig. 1b, c).

At various times after plating, the number of phase-bright neuronal somata was estimated by counting about 30 fields (×200 magnification) chosen at random and normalizing for the total area of the dish. In typical platings there were 15-20 neurones per field and these were evenly distributed throughout the dish. The cultures were then extracted using 2M acetic acid and the extracts lyophilized. The amount of SP and SOM present in a culture was assayed by radioimmunoassay. Antibody R6P was used for the SP assay as previously described 17 The SOM assay used was a modification of that described elsewhere 18. Briefly, the SOM assay used antibody M4 with ¹²⁵I-tyrosinyl-SOM as a tracer. The incubation and separation procedures were essentially the same as those used for the SP assay. SOM standards were prepared using cyclic-SOM (Boehringer Mannheim) and the concentrations checked by amino acid analysis. When extracts of neurones plus nonneuronal cell cultures were chromatographed on a gel-filtration column (Sephadex G-25-80; Sigma), over 85% of both the SPand SOM-immunoreactive material eluted as single peaks in the same volume as either synthetic SP or synthetic SOM. (The fact that only one peak of SOM is present in the extracts of DRG cultures is noteworthy, as a variety of tissues, including adrenal , contain SOM-immunoreactive material of several different molecular weights when assayed using the same antibody).

The peptide content of cultures containing either neurones alone or neurones plus non-neuronal cells is shown in Fig. 2. The cells plated on to each dish (from five ganglia) contained 35 fmol of SP and 120 fmol of SOM when freshly dissociated. During the next 2 weeks, the content of SP in the cultures of neurones alone increased ~75-fold and then reached a plateau, while the content of SOM remained low; the ratio of SOM/SP was 0.03 at

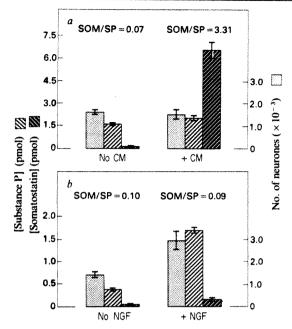

Fig. 3 Effect of conditioned medium and NGF on levels of SP and SOM and on DRG neuronal survival. a, Neurones-alone cultures were fed every day for 11 days with medium containing 33% conditioned medium (CM); control cultures received only fresh medium (all media contained 1 µg ml⁻¹ NGF). Results are mean ±s.e.m. of triplicate cultures. Ganglionic non-neuronal cells without neurones were obtained by removing from the cultures neurones, together with non-neuronal cells, using trypsin, filtering the mixture through lens paper, re-plating and irradiating the cells when confluent; neurones do not survive this treatment. Medium incubated for 2 days with such cultures provided the conditioned medium. Aliquots of conditioned medium and the ganglionic non-neuronal cells were also assayed for SP and SOM. b, Neurones-alone cultures were fed for 11 days with medium either with or without the addition of NGF at a protein concentration of $1 \mu g \text{ ml}^{-1}$. NGF was prepared from mouse salivary glands²⁶. Results are mean ±s.e.m. of triplicate cultures.

2 weeks and 0.13 at 4 weeks. However, when the neurones were grown together with ganglionic non-neuronal cells, the content of SOM steadily increased after the first week of culture (the time at which the non-neuronal cells are confluent) and after 2 weeks and 4 weeks, the ratio of SOM/SP was 0.96 and 6.34. respectively (Fig. 2a, b). This increase in SOM content could not be attributed to a general effect on neuronal growth, because it was not associated with an increase in SP content. Indeed, the content of SP in the presence of non-neuronal cells was suppressed by $\sim 50\%$ at all time points (Fig. 2a). The number of neurones surviving in culture remained constant from the first day after plating, for 3 weeks in culture, while in the fourth week there was a 20% loss of neurones (Fig. 2c). There was no detectable difference within the limits of the counting procedure in neuronal survival in the presence or absence of non-neuronal cells.

To determine whether the non-neuronal cells had to be in contact with the neurones to influence the production of SOM, cultures of neurones alone were fed with medium that had been conditioned by incubation with ganglionic non-neuronal cells without neurones. Such conditioned medium markedly increased the SOM/SP ratio without detectably influencing neuronal survival (Fig. 3a). This experiment also showed that it was the neurones which increased their SOM content, as neither the non-neuronal cells nor the conditioned medium contained detectable amounts of SOM or SP.

Although NGF is known to affect the development 20,21 and SP content^{22,23} of sensory neurones and is produced by cultured non-neuronal cells²⁰, it is unlikely to be the agent responsible for the change in relative amounts of SOM and SP in these experiments. When NGF was added to cultures of neurones alone, it doubled the number of neurones which survived and increased

both SOM and SP proportionately, but did not significantly alter the ratio of SOM/SP (Fig. 3b). Moreover, all the experiments demonstrating the effect of non-neuronal cells or conditioned medium on the SOM/SP ratio were done in saturating levels of NGF.

The survival of sensory neurones depends on additional factors distinct from NGF which are present in brain extracts and secreted by a glioma cell line²¹. In my experiments, the 5% chick embryo extract (CEE) present in the medium presumably provided some factor which supported the survival of neurones in the absence of added NGF. As CEE was present in all the experiments reported here and, again, because the change in SOM/SP ratio occurred without a change in neuronal survival, the 'survival factor' demonstrated by Barde et al.21 is also unlikely to be the factor which increased SOM content. Furthermore, when an extract of embryonic chick brain² $(100 \ \mu g \ ml^{-1} \ protein)$ was added to cultures of neurones alone for 2-10 days after plating, SP content was increased ~two-fold and SOM rather less; thus there was little effect on the SOM/SP ratio.

These results demonstrate that, like sympathetic neurones. sensory neurones respond to a factor from non-neuronal cells that dramatically influences peptide synthesis. This change in the relative content of SOM and SP is distinct from previously described influences on neuronal survival in the ganglia. It is not known whether, analogous to the switch in adrenergic-cholinergic properties of sympathetic neurones¹, a single population of developing sensory neurones is capable of making either SP or SOM. It is also unknown whether the levels of CCK and VIP can be similarly influenced, nor is it clear what part this effect plays in normal development of sensory neurones. However, in view of the diversity of peptides present in sensory (and autonomic) ganglia, it is possible that the soluble factor described here may represent one of the differentiation signals required for development of neural crest cells.

As DRG non-neuronal cells consist of two major cell types, glial cells and fibroblasts, it is of interest to know which type of cell is influencing the relative levels of SOM and SP. Experiments using purified cultures of either Schwann cells or fibroblasts from DRG²⁵ or autonomic ganglia should establish this point and provide a well defined system for extending these observations.

I thank Drs G. D. Fischbach and S. E. Leeman for their support and encouragement of this work. I also thank P. H. Patterson for his encouragement and advice. The somatostatin antibody was a gift from M. Arnold and J. Fernstrom. This work was supported by NIH grant NS11160 to G. D. Fischbach and AM1651007 to S. E. Leeman, A.W.M. was supported by NIH training grants GM00919 and NS07009.

Inability of tolerant males to sire tolerant progeny

R. N. Smith

Department of Reproductive Biology, Case Western Reserve University, Cleveland, Ohio 44106, USA

Recent data of Gorczynski and Steele suggested that male mice made tolerant of an allogeneic strain by the neonatal injection of hybrid lymphomyeloid cells may, by a presumably genetic mechanism, pass on this operationally similar form of hyporesponsiveness to their progeny 1,2—the progeny have inherited an acquired characteristic. Their theory, proposed to account for the inheritance of an acquired characteristic, uses a RNA tamour virus that transfers to the spermatogenic germinal epithelium DNA coding for the gene products of the foreign alloantigens. This is possible because the tolerant mouse is chimaeric and contains small numbers of foreign lymphomyeloid cells. Thus, the virus transfers genetic information for transplantation antigens from the chimaeric foreign cells to the germinal epithelium of the host. The progeny of the tolerant male are themselves tolerant because they have received DNA coding for the foreign antigens from paternal sperm. The progeny are tolerant because foreign is now 'self'. I have now repeated these experiments in a strain combination of rats, DA tolerant of PVG, and found no hyporesponsiveness to the PVG strain in the progeny of tolerant DA males.

Neonatally induced transplantation tolerance requires the acceptance of an allogeneic skin graft³, and such tolerance seems coincidental with the inability of lymphocytes from these skingraft-tolerant animals to generate cytotoxic lymphocytes against alloantigens of the tolerated strain^{4,5}. In addition, the lymphocytes of some tolerant animals are incapable of proliferation in the mixed lymphocyte culture (MLC) when stimulated by alloantigens of the tolerated strain^{4,6}. These lymphocytes are also able to transfer adoptively specific tolerance to sub-lethally irradiated syngeneic recipients^{4,7}. These four criteria were used to analyse the tolerant state of DA males made neonatally tolerant to PVG, and to analyse the relative responsiveness to PVG alloantigens of the DA progeny of these tolerant males.

DA neonates from three litters (20 pups) were made tolerant of PVG by the injection into the tail vein of 1×10° spleen and bone marrow cells from (PVG×DA)F₁ hybrid female donors. Injections of 0.1 ml using a 30-gauge needle were given within 24 h of birth. At 6 weeks of age, all putatively tolerant DA rats—18 of the surviving animals—were grafted with PVG ear skins, and of these, 14 accepted PVG grafts for 60 days without evidence of rejection. The skin-graft-tolerant rats were also analysed to determine if their peripheral blood leukocytes (PBL) could be stimulated by PVG alloantigens in the MLC, a sensitive assay used to detect reactivity to allogeneic determinants^o. DA males that accepted PVG skin grafts for 60 days and had PBL which were not stimulated by PVG alloantigens in the MLC, were allowed to sire, one litter with a normal DA female. The tolerant males were cannulated and their thoracicduct lymphocytes (TDL) analysed in quantitative MLC and cytotoxic lymphocyte culture (CTL) assays for their ability to respond to PVG and third party Lewis alloantigens. In addition, 1×10° TDL from these tolerant males were transferred adoptively to sub-lethally irradiated (500 rad) DA recipients to determine if the TDL from tolerant males could transfer unresponsiveness to secondary recipients against PVG antigens^{4,7}. Six of the eight males met the four criteria of tolerance to transplantation alloantigens—acceptance of skin grafts, unresponsiveness in the MLC and CTL assays to PVG

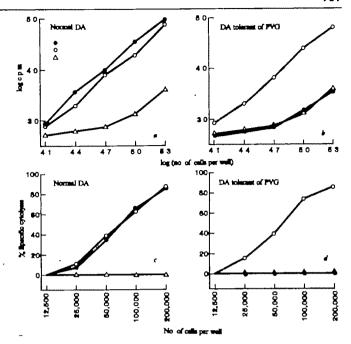

Fig. 1 A representative experiment of the mixed lymphocyte culture (MLC) and cytotoxic lymphocyte culture (CTL) in which responding cells are titrated against a constant number of stimulating cells. The relative estimates of frequency in Table 3 are derived from this type of experiment. Stimulators and targets: Δ, DA; •, PVG; O, Lewis. The MCL was used as a quantitative assay following procedures described elsewhere 10 in which serial dilutions of responder TDL were added to an excess of irradiated stimulator spleen and lymph node cells in a constant volume of 0.2 ml per round-bottomed microtitre well. Cells were cultured in RPMI 1640 containing 5% fetal calf serum (FCS), 2 mM ghitamine, M 2-mercaptoethanol and antibiotics. The FCS was selected for its ability to support the generation of cytotoxic lymphocytes without high spontaneous proliferation. Stimulator cells were spleen and lymph node cells pooled from one donor and were irradiated with 1,000 rad. The MLC was incubated for 4 days at 37 °C in a humidified CO2 incubator. During the last 4h of incubation each well contained 1.0 μCl of ³H-methylthymidine (15 Ci mmol⁻¹), added in 0.01 ml of phosphate buffered saline. The cells were collected on a semi automatic harvester. The same quantitative approach was used to assay the potential cytotoxic activity of a responder population. Cytotoxic activity was measured in wells from titrated MLC responses on day 5. 0.1 ml of culture supernatant was removed from each well and replaced with 0.1 ml of target cells (10⁵ per ml). The plates were spun at 500g at room temperature for 10 min and incubated at 37 °C for 4-6 h in a humidified CO2 incubator. To terminate the cytotoxic experiment, plates were placed on ice and 0.1 ml removed for counting. Target cells were 3-day Con A blasts prepared from lymph node cells in complete medium with 2.5 μg ml $^{-1}$ Con A. Target cells $(2-3\times10^{7})$ were labelled for 1-2 h with 50-100 μ Ci of 51 Cr sodium chromate (Amersham), washed and then resuspended in complete medium.

alloantigens and the ability to transfer suppression (Table 1, Fig. 1). Responses to the Lewis strain, the third party control, were normal, indicating that the tolerance and suppression were specific for PVG antigens.

Half of the progeny (21 DA rats) of the six tolerant males were analysed by quantitative MLC and CTL assays¹⁰, and half were skin grafted with (PVG×DA)F₁ ear skin. Males were grafted with male skin and females with female skin. The data on skin graft rejection (Table 2) indicate that the progeny of the tolerant DA males rejected PVG grafts and third party Lewis grafts at the same rate as did normal DA rats. Thus, there was no evidence of tolerance by this assay.

As the rate at which skin grafts are rejected might not detect subtle and weak hyporesponsiveness, the remaining progeny were analysed to estimate their response to PVG and Lewis alloantigens, as measured by MLC and CTL assays¹⁰. The number of DA TDL responding to PVG and Lewis alloantigens

A 1041 17. . . .

was titrated to generate a dose-response curve. The advantage of this type of analysis is that displacement along the x-axis represents the relative change in the frequency of cells reactive to the stimulating antigen¹⁰. The relative frequency between control and experimental groups may be related by comparing the required number of cells, determined by regression, needed to give a certain response. For the MLC assays the number of cells required to give 10,000 c.p.m. ³H-thymidine incorporation was chosen to relate the relative frequency between animals, and the number of cells required for 33% specific cytolysis was chosen as the estimate of frequency for the CTL assay. The data in Table 3 indicate that the relative response of DA TDL from either normal DA rats or DA rats that were the progeny of tolerant males is the same with respect to PVG alloantigens.

These results suggest that, in this strain combination of rats, tolerance or any weak hyporesponsiveness to transplantation antigens cannot be transmitted to the progeny of tolerant rats. Thus, acquired tolerance could not be transmitted genetically. Although these results clearly cannot confirm those of Gorczynski and Steele^{1,2}, they do not falsify their theory that a virus, which includes in its genome some DNA coding for the tolerated transplantation antigens, could infect spermatogenic germinal epithelium. The resulting sperm would render progeny tolerant because the foreign alloantigen is now self. Presumably, genetic information for other immunological phenomena, for example,

At the time of cannulation for thoracic-duct lymphocytes (TDL), each DA male tolerant of PVG was 3-4 months old and had not yet rejected a PVG graft 60-90 days after grafting.

According to Dorsch and Roser7. Four DA rats, irradiated with 750 rad (a sublethal dose), were grafted with both PVG and Lewis ear skin and injected intravenously with 5×10^7 TDL from the indicated donor.

anti-idiotypic antibodies, could also be transmitted, and in this way account for the tolerant progeny.

Because viruses show host specificity, that is, preferentially infect certain species or even subgroups of a species, it is possible that mice could transmit genetically acquired tolerance, but that other species, for example, rats, could not.

An additional experiment relevant to the interpretation of the experiments of Gorczynski and Steele is the backcross $(A \times B)F_1$ male \times A female. The hybrid male, $(A \times B)F_1$, and the male, A, made tolerant of B are similar in that both have acquired a state of tolerance to B. If such tolerance to B can be transmitted genetically by sperm haploid for A, then less than 50% of the progeny of the backcross should respond to B. As far as I am aware, this is not the case—50% of such progeny are histoin-

Table 2 Skin graft rejection of the progeny of tolerant male rats

Group	No. of animals	Rejection (days) (MST ± 1 s.d. (Range))	
Normal DA rats	20	PVG 7.75±0.72 (7-10)	Lewis 7.9 ± 0.85 $(7-10)$
Progeny of DA males tolerant of PVG	21	7.95 ± 0.87 $(7-10)$	7.81 ± 0.87 $(7-10)$

All rats were doubly grafted with ear skin from PVG (left flank) and Lewis (right flank)

Table 3 Relative response to PVG alloantigens by thoracic-duct lymphocytes

		MLC assay	
N	Status of DA rats	Slope (mean ± s.d. (range))	No. of cells to give 10,000 c.p.m. (mean ± s.d. (range))
10	Normal	1.64 ± 0.15	$49,860 \pm 4320$
		(1.38-1.84)	(41,188-57,833)
21	Progeny of males	1.70 ± 0.18	$52,495 \pm 5950$
	tolerant of PVG	(1.41-1.86)	(40,599-63,495)
		CTL assay	
		Slope	No. of cells to give
		(mean ± s.d. (range))	33.3% specific lysis
10	Normal	85.6 ± 7.4	$49,279 \pm 12,226$
		(76-94)	(45,481-65,234)
21	Progeny of males	84.3 ± 6.3	47.321 ± 10.119
	tolerant of PVG	(73-93)	(33,258-64,145)

Dose-response curves were done for each animal as described for Fig. 1, and the data analysed by simple linear regression. The relative response to PVG alloantigens was computed for each animal as the number of cells required to incorporate 10,000 c.p.m. of ³H-thymidine or give 33.3% specific lysis of PVG of concanavalin A (Con-A) blasts labelled with ⁵¹Cr. Normal and experimental groups are not different statistically by Student's t-test. The correlation coefficient was >0.95 for all regression lines. P > 0.2 for the normal and experimental groups in both the MLC and CTL assays

compatible to B. Because of the generally accepted results of this type of experiment, I believe it is unlikely that 'antigen' is being transferred genetically, and thus this does not explain why tolerant males should pass on their tolerance to their progeny.

Of course, the point of Gorczynski and Steele's work is that genetically transmitted acquired characteristics in mice is not the usual form of inheritance, and that such an event is truly exceptional. It is hoped that the experiments of Gorczynski and Steele^{1,2} can be repeated in the same strains of mice which they used, preferably derived from the same stock.

Two major genes, linked to HLA and Gm, control susceptibility to Graves' disease

Graves' disease is a multifactorial disease in which immunogenetic as well as environmental factors have important roles. Recently, cumulative evidence has shown that genes controlling immune responses are linked to the MHC (major histocompatibility complex)1 and/or immunoglobulin allotype genes2,3. To identify the genes governing susceptibility to Graves' disease, we have studied 30 Japanese families where more than two first degree relatives were affected with the disease. From genetic analysis of HLA (human MHC) and immunoglobulin allotype of all family members, we present here evidence for the existence of two genes controlling the susceptibility to Graves' disease, one closely linked to HLA-DR, the other linked to the gene coding for the Gm allotype.

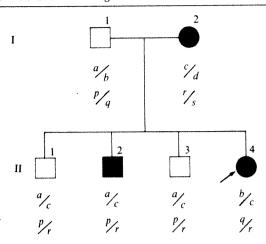

Fig. 1 A family affected with Graves' disease. ● ■, Graves' disease. a: HLA-A26, Bw54, Cw1; b: HLA-A2, Bw54, -; c: HLA-A11, Bw39, -; d: HLA-A2, -; p: Gm(1, 13, 15, 16, 17); q: Gm(1, 17, 21); r: Gm(1, 3, 5, 13, 23); s: Gm(1, 13, 15, 16, 17).

The families comprised 189 members, 71 (37.6%) of whom were affected with Graves' disease (60 female). The diagnosis of Graves' disease was based on the history and signs of hyperthyroidism with diffuse goitre, increased ¹³¹I uptake, raised serum thyroid hormone levels, the presence of thyroid autoantibodies, a positive stimulation test to thyrotropin releasing hormone (TRH test) and triiodothyronine suppression test, and histological examination if necessary. All these examinations except the triiodothyronine suppression test were also applied to healthy family members. They were typed for HLA-A, -B, -C and -DR antigens and immunoglobulin allotypes, Gm and Km.

We analysed the segregation of Graves' disease and HLA and Gm haplotypes in 15 selected families. We identified the disease-associated haplotypes of HLA and Gm by determining the haplotypes shared between two affected siblings selected if necessary by random number. We found that all affected siblings except one female shared the disease-associated haplotypes of both HLA and Gm. However, siblings who shared the diseaseassociated haplotypes did not necessarily suffer from the disease (Fig. 1). Statistical significance of this genetic association between the development of Graves' disease and particular HLA and Gm haplotypes in each family was analysed by the sib-pair method⁴ using 62 siblings in the families. Siblings under 10 yr old were excluded from analysis because Graves' disease is very rare below this age (Table 1). A significant association between the development of Graves' disease and particular HLA and Gm haplotypes in each family was observed ($P < 2.0 \times$ 10⁻³). The association was strong and significant in female siblings ($P < 2.0 \times 10^{-3}$), but not significant in male siblings, partly due to the small numbers of male patients in these families. The strong association between the development of Graves' disease and HLA and Gm haplotypes indicated that there might be two genes linked to HLA and Gm, respectively, which had a major influence on the development of Graves' disease. The one affected female sibling who did not share the disease-associated haplotype of HLA with other affected siblings could be explained by a recombination between HLA and an HLA-linked susceptibility gene for Graves' disease. Fourteen healthy siblings who had the disease-associated haplotypes were aged from 12 to 49 yr (mean age 27.6 yr). Because the age of onset of Graves' disease varies widely, they may possibly develop the disease later in life.

Furthermore, in a study of 30 probands in these families, the antigen frequency of HLA-DR5 was significantly increased to 30.0%, compared with 5.0% in control group ($Pc < 3.0 \times 10^{-3}$). The association between Graves' disease and HLA-DR5 indicated that an HLA-linked disease susceptibility gene was in strong linkage disequilibrium with HLA-DR5 (Table 2). There was, on the other hand, no significant association between

Table 1 Association between Graves' disease and HLA and Gm haplotypes in 15 families

		haple of HLA and	associated otypes I Gm allotype Negative†	P

* Positive for disease-associated HLA and Gm haplotypes.

Graves' disease and any particular immunoglobulin allotype in these probands, indicating the absence of significant linkage disequilibrium between Gm and a Gm-linked disease susceptibility gene.

The HLA-D region is assumed to be comparable to the I-region of the murine H-2 complex, in which immune response genes (Ir genes) and immune suppression genes (Is genes) are located^{5,6}. Recently, it has become more evident that HLA-linked Ir genes or Is genes exist in man⁷⁻⁹. Analysis of a human population has also revealed a statistical association of Gm allotypes with immune responsiveness to specific antigens^{10,11} and with several autoimmune diseases^{12,13}.

In the murine system, it has been demonstrated that idiotypic determinants are linked to heavy-chain constant region allotypic markers^{14,15}, and the idiotypic determinants of antigen-specific receptors on lymphocyte membranes are likely to have

Table 2 Association between Graves' disease and HLA

fundamental roles in immune regulation¹⁶. The immuno-regulatory function of idiotypes was revealed in deliberate immunization experiments¹⁷. It was therefore assumed that two genes, HLA-linked and Gm-linked, would govern the specific immune response to certain antigen(s) relevant to the development of Graves' disease. The elucidation of the antigen(s), and environmental factors involved in the pathogenesis of Graves' disease will, in turn, help to clarify the immunogenetic factors controlling the susceptibility to Graves' disease.

This is the first description of a strong association between a human disease and not only HLA but also immunoglobulin allotype in a familial analysis.

Association between HLA-DR antigens and helper cell activity in the control of dental caries

Thomas Lehner, Jonathan R. Lamb. Kenneth L. Welsh & Richard J. Batchelor

Department of Oral Immunology and Microbiology, Guy's Hospital Medical and Dental Schools, London SE1 9RT, UK Department of Tissue Immunology, Royal Postgraduate Medical School, The Hammersmith Hospital, London W12 0H5, UK

Dental caries affects the majority of people in developed countries but about 3% of them seem to be resistant. An immunological basis for this resistance has been suggested by the findings that relatively caries-free subjects have increased serum antibody titres1 and that their T lymphocytes have a greater potential to proliferate on stimulation with streptococcal antigens2. Helper cells or their factors3 are required for formation of antibody to the streptococcal antigen4. In this study specific helper factor activity was released by 1-10 ng of the purified streptococcal antigen I/II (SAI/II) from lymphocytes of cariesresistant subjects, compared with 1,000 ng of SAI/II required to release similar helper factor activity from lymphocytes of cariesprone subjects. The low-dose helper activity of lymphocytes was associated predominantly with the HLA-DRw6,1,2,3 crossreactive groups, whereas the high-dose helper activity was associated with the HLA-DR4-related gene product.

The most important microorganism to be identified as a causative agent of dental earies is Streptococcus mutans⁵ purified protein antigen (SAI/II) isolated from this organism^{6,7} induced protection against caries on immunization of rhesus monkeys⁸. SAI/II stimulates monkey peripheral blood lymphocytes to generate T helper cells after in vitro incubation for 4 days in a modified Marbrook-Diener system⁴. Further incubation of the helper cells with an optimum dose of SAI/II for 24 h releases antigen-specific helper factor (HF) which stimulates a cooperative antibody response by normal mouse spleen cells to dinitrophenylated SAI/II (DNP-SAI/II). We have now modified this entirely in vitro method of generating both helper cells and factors, by assuming that in vivo natural immunization in man and artificial immunization in rhesus monkeys should lead to generation of helper cells. We have then used 1-10,000 ng of SAI/II to stimulate the relase of HF from the putative helper cells.

We selected a population of 24 young subjects (mean age 23 yr), 12 of whom showed a low DMFS index (decayed, missing, filled tooth surfaces) of 0-3 (mean \pm s.e., 1.0 ± 0.4), and the remaining 12 showing a high DMFS index of 5-35 (18.8 ± 3.0). Lymphocytes from the caries-resistant subjects released HF on addition of 1-10 ng SAI/II, whereas lymphocytes from

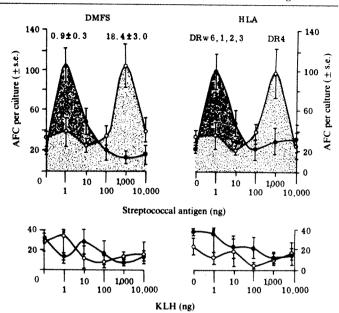

Fig. 1 The effect of dose of streptococcal antigen I/II (SAI/II) on the T-cell helper function in caries-resistant and caries-prone subjects. Human peripheral blood lymphocytes were separated by Ficoll–Isopaque density gradient $^{18}.5 \times 10^6$ viable cells per ml were cultured with 1, 10, 100, 1,000 and 10,000 ng of SAI/II $^{6.7}$ or keyhole limpet haemocyanin (KLH) for 24 h in Marbrook flasks⁴ The cell-free supernatant (HF) was collected, Millipore filtered and 1 μl of the HF was assayed in Marbrook-Diener culture flasks with 10⁷ unprimed B10.BR spleen cells and 0.1 μg ml⁻¹ DNP-haptenated SAI/II or TNP-KLH⁴. The anti-DNP antibody-forming cells (AFC) were assayed on day 4 in triplicate using the modified Cunningham assay¹⁹. The results are expressed as the number of AFC per culture ± s.e.m. and are given for the low DMFS (decayed, missing and filled surfaces; n = 12) and high DMFS group (n = 12) on the left, and DRw6,1,2,3 (n = 14) and DR4 group (n = 10) on the right. Lymphocytes responding to 1-10 ng SAI/II (DMFS 1.0 ± 0.4; HLA-DRw6,1,2,3) are shaded and those responding to 1,000 ng SAI/II (DMFS 18.8 ± 3.0; HLA-DR4) are stippled.

caries-prone subjects required 1,000 ng SAI/II for a similar release of HF, assessed by the antibody-forming cell assay (Fig. 1). Indeed, 11/12 (92%) of the caries-resistant, compared with 3/12 (25%) caries-prone subjects, released a significant amount of HF from lymphocytes stimulated with 1-10 ng SAI/II (P =0.0027 by Fisher exact test). In contrast, 8/12 (68%) of the caries-prone subjects and 0/12 caries-resistant subjects released a significant amount of HF from lymphocytes stimulated with 1,000 ng SAI/II (P = 0.0013). Significant HF was taken as the mean + 3 s.d. (79) antibody-forming cells resulting from the HF activity released by lymphocytes in the absence of SAI/II in 24 subjects.

The striking difference in the dose response to the SA between the disease-resistant and prone subjects was then analysed in relation to the HLA-A,B,C and DR(w) antigens' There were no obvious differences with the HLA-A.B and C antigens but a significant relationship was observed with the HLA-DR antigens (Fig. 1). Stimulation of lymphocytes with 1-10 ng SAI/II released significant amounts of HF activity in 7/9 subjects with DRw6, as compared with 1/10 with DR4 (P = 0.0097). Furthermore, a smaller group of five DR1,2,3typed lymphocytes also showed a significantly greater number of lymphocytes responding to the lower dose of SAI/II than the DR4-typed lymphocytes (P = 0.0039). It seems, therefore, that the cross-reacting DRw6,1,2,3 antigens¹⁰ are associated wih helper cells responding to low doses of SAI/II (12/14) whereas the DR4 antigens are not (1/10; P = 0.00074). However, lymphocytes with DR4 responded to 1,000 ng SAI/II in 6/10 (60%) subjects, compared with 3/14 (14%) subjects with lymphocytes bearing DRw6,1,2,3 antigens (P = 0.0566). Note that DR4 seems to be functionally dominant, because in all 10

Table 1 Reproducibility of the dose responses of antibody-forming cells of lymphocytes

			ng of streptococcal antigen I/II					
Subject	DRw	No. of times tested	0	1	10	100	1,000	10,000
1 2 3 4	6 6 4 4	4 3 5 3	21.8 (2.8) 15.3 (2.9) 22 (3.3) 15.3 (2.9)	127.2 (7.2) 84.7 (30.4) 34 (5.6) 15 (4)	15.8 (5.6) 93 (15.1) 40 (20) 45 (15)	31.3 (14.4) 14.3 (9.8) 34.3 (1.3) 43 (12)	16.8 (7.1) 15.7 (8.7) 136.5 (12.6) 133.3 (20.3)	17.5 (5.9) 12.3 (4.7) 47.7 (3.9) 60 (21.6)

Results are the mean (±s.e.) of antibody-forming cells (AFC). The AFC of human peripheral blood lymphocytes were determined to five concentrations of streptococcal antigen I/II, as described in Fig. 1 legend. This was performed on three, four or five occasions on lymphocytes from the same four donors.

subjects in whom DR4 was associated with DRw6,1,2,3 the lymphocytes responded to the high dose of SAI/II. The reproducibility of the effect of increasing doses of SAI/II on lymphocytes was tested on three to five different occasions in four subjects (Table 1). The maximum number of antibodyforming cells resulted from 1-10 ng SA for DRw6 or 1,000 ng for DR4 on each of the 15 occasions tested; the variations between different tests in the same subjects were small, as shown by the standard errors of the means.

A parallel study of HF activity of in vivo immunized, cariesresistant monkeys with SAI/II revealed that lymphocytes from these monkeys responded to 1-10 ng of SAI/II but not to keyhole limpet haemocyanin (KLH; Fig. 2). However, cariesprone monkeys which were not immunized showed no response to any of the antigen concentrations. The results of naturally acquired immunity in man and artificially acquired immunity in monkeys suggests that protection against dental caries in both primates is associated with T helper cells capable of responding to 1-10 ng SAI/II; this might be controlled in man by the cross-reactive DRw6,1,2,3 gene products. However, the cariesprone subjects have T cells which require a 1,000 times higher dose of SAI/II to respond with a HF activity comparable to cells of the caries-resistant subjects, and DR4 may be one of the gene products controlling this response. As such a high dose is unlikely to be reached in biological conditions, the end result might be similar to that found in monkeys which failed to respond to any of the antigen doses.

The specificity of the HF to DNP-SAI/II and characterization of HF have been described for rhesus monkeys elsewhere 4.11. Corresponding specificity studies have been carried out on human lymphocytes. Culturing human or monkey lymphocytes with 1-10,000 ng KLH and using trinitrophenyl (TNP)-KLH in the cooperative culture had no effect on the number of antibodyforming cells (Figs 1, 2). To exclude further the possibility that the SAI/II might stimulate a nonspecific helper factor, the factor was added to the cooperative culture with TNP-KLH. This had no effect on the number of antibody-forming cells (22.5 \pm 7.4, n = 4), as compared with the same four factors added to the cooperative culture with DNP-SAI/II, which increased the antibody-forming cells to 115.0 (\pm 2.2).

Immunoadsorption of HF on Sepharose 4 beads coated with SAI/II bound the HF activity but did not do so when the beads were coated with KLH (in preparation). Furthermore, as with monkey HF11, human HF was bound by antisera to anti-HF, but not anti-suppressor factor antisera. The factor also had DR region-encoded determinants, as insolubilized monoclonal anti-DR framework antibody (DA2) bound HF. Moreover, a monoclonal antiserum to DRw6,1,2 (Genox 353) absorbed out all the helper activity of DRw6 lymphocytes, without any effect on the helper activity from DR4 lymphocytes (in preparation). The factor binds IgM but not IgG or IgA antisera, as has been found in mouse and monkey helper factors 11-13. The significance of IgM has not been adequately explained, but it has been interpreted as a cross-reaction with some region of the μ chain. It seems, therefore, that HF prepared from human lymphocytes has, in addition to an antigen-binding site, a 'constant' region and determinants encoded by the HLA-D region, as has been found in HF prepared from mouse lymphocytes¹⁴

The finding that T helper cells respond to either low or high doses of antigen in man has no direct parallel in animal experiments. T-cell involvement has been observed in low responder mice, for in addition to the decreased antibody formation there is a decrease in delayed hypersensitivity and in vitro T-cell proliferative response¹⁵. Furthermore, immunization with an antigen under Ir gene control showed that in high responder mice the number of antigen-specific T cells increases, whereas no change occurs in the low responders¹⁶. The association of low-dose T helper cell responses in man with the DRw6,1,2,3 cross-reactive antigens and high-dose helper responses with DR4-related antigen might be an expression of , gene control. However, in vitro secondary responses to KLH revealed that human T-cell monocyte interactions are governed by HLA-D region antigens¹⁷. It is therefore possible that the functional high- and low-dose responses to SAI/II which are associated

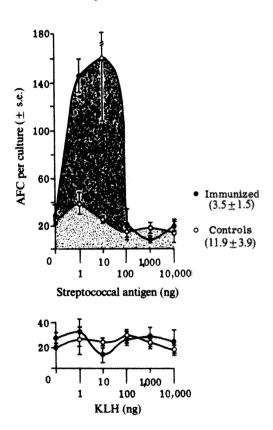

Fig. 2 The effect of streptococcal antigen I/II (SAI/II) T-cell helper function in immunized and control monkeys. Rhesus monkey peripheral blood lymphocytes were separated and cultured with 1, 10, 100, 1,000 and 10,000 ng of SAI/II or KLH. HF was prepared and the AFC were assayed and expressed as described for human lymphocytes in Fig. 1 legend. The results are given for six monkeys immunized with SAI/II and with a scare of 1.8 (±3.9). Lymphocytes responding to 1-10 ng of SAI/II (DMFS of 3.5) are shaded and there are no lymphocytes responding to 1,000 ng of SAI/II among the control monkeys.

with the HLA-D region may be related to monocyte antigenbinding cells and not necessarily to T cells. This possibility will be examined, although preliminary results with radiolabelled SAI/II suggest that selective binding of small doses of SA to HLA-DRw6,1,2,3 cells and high doses to HLA-DR4 cells are related to T cells. Whichever set of cells is involved, it seems that the aims of immunization should be to induce with very small doses of protein antigen T helper cells which cooperate with B cells in the formation of high-avidity antibodies, required in protection against the microorganisms.

We thank Dr M. Crumpton for antisera and Miss Janet Avery for technical assistance. This investigation was carried out under a MRC project grant.

Cross-reactivity between Thy-1 and a component of intermediate filaments demonstrated using a monoclonal antibody

R. Dulbecco*, M. Unger, M. Bologna†, H. Battifora†, P. Syka & S. Okada

The Salk Institute, 10010 N. Torrey Pines Rd, La Jolla, California 92037, USA and *Department of Pathology and Medicine, University of California at San Diego, La Jolla, California 92037, USA

Monoclonal antibodies1 are powerful tools for identifying antigenic molecules because they recognize a single antigenic site. In contrast, conventional immune sera contain mixtures of antibody molecules with a large variety of specificities. Some of these specificities may be cross-reactive with antigenic sites present on unrelated molecules, thus tending to decrease the overall recognition specificity. Such a cross-reactivity should be observed with some monoclonal antibodies, in which it might be expected to be both strong and specific (that is, directed against a restricted number of targets2). We report here such a crossreactivity in a monoclonal antibody that recognizes equally well both Thy-1 (ref. 3) and a component of intermediate filaments, probably vimentin^{4,5}.

The hybridoma producing the monoclonal antibody in question was isolated by Lake and Clark⁶. This antibody is an anti-Thy-1.1 mouse IgM designated T11A9e, which binds to Thy-1 at the surfaces of various cells, for example, the fusiform derivatives of the mammary cells RAMA7,8 and RANI9 or the

Fig. 1 Immunofluorescence of T11A9e serum with F2408 cells. a, A glass cover slip on which cells had grown was washed in phosphate-buffered saline (PBS) containing 0.01% Na azide and was then covered with antiserum diluted 1/50 in the PBS-azide saline. After 30 min, it was washed three times with PBS-azide, then overlayered with a 1/50 solution of fluorescein-labelled goat anti-mouse immunoglobulin (Antibodies, Inc.) for 30 min, washed again three times and mounted. Similar staining, of slightly reduced intensity, was obtained if the cells were fixed in 3% formaldehyde for 20 min, b. The cover slip was fixed in 3% formaldehyde for 20 min, rinsed in PBS-azide containing 0.01% thymerosal, dipped in cold methanol and then acetone (30 s each), hydrated in PBSazide and then stained as in a, except that the three washings after each antibody application were for 10 min, 2 h and 10 min. Similar results were obtained if formaldehyde fixation was omitted. The disappearance of the Thy-1 surface dots was observed for all antisera. Photographed using a Zeiss microscope with epi-illumination. a, $\times 1,300$; b, $\times 900$.

F2408 rat fibroblasts 10 (Fig. 1a). In the present experiments, the antibody used was either in the form of serum obtained from mice in which the T11A9e hybridoma had given rise to a tumour after subcutaneous injection, ascitic fluid after intraperitoneal cell injection, or supernatant of the hybridoma cultures. The IgM in the supernatant was partially purified and concentrated about 30 times by retention on an Amicon XM300 filter, followed by sizing in a Biogel A5M column. All these preparations had identical specificities.

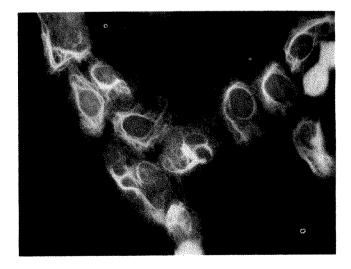

Fig. 2 Immunofluorescence of F2408 cells treated with colchicine. Cover-slip cultures were grown for 18 h in the presence of colchicine, 20 µg ml⁻¹, then stained with T11A9e serum as described for Fig. 1b. ×700.

[†] Permanent addresses: Department of Pathology, University of L'Aquila Medical School, L'Aquila, Italy (M.B.) and Department of Surgical Pathology, Northwestern University Medical School, Chicago, Illinois 60611, USA (H.B.).

Immunofluorescence experiments showed that T11A9e stains, in addition to surface Thy-1 in unfixed cells, a system of filaments in methanol-acetone-treated cells. Stained filaments were seen in the fusiform but not in the epithelial derivatives of mammary cells, and in the F2408 fibroblasts (Fig. 1b). They were also stained in cells that do not contain a Thy-1.1 antigen on their surfaces, such as BALB/c macrophages or BALB/c 3T3 fibroblasts, which have Thy-1.2. In all cells the pattern resembled that of intermediate filaments stained by antibodies to vimentin. In fact, in double immunofluorescence experiments, an identical network was stained in F2408 cells using either T11A9e or a rabbit antiserum to vimentin (Fig. 2). In cells pretreated with colchicine (20 µg ml⁻¹) for 12 h, the filaments stained by T11A9e showed the behaviour reported for intermediate filaments4 (Fig. 3). To exclude the possibility that the ability to stain these filaments was due to an accidental contamination of the hybridoma culture with hybridoma cells producing a different antibody, the T11A9e hybridoma was recloned. This recloned hybridoma produced an antibody with the same properties.

To determine whether the same antibody molecules stained Thy-1 and intermediate filaments, a T11A9e antiserum was absorbed with cells of two Thy-1.1-positive thymoma cell culture lines, or their Thy-1 negative derivatives¹¹. The ability to stain the filaments was absorbed by the Thy-1-positive cells but not by their negative variants; it was not absorbed by Thy-1.2 cells, whether positive or negative for Thy-1 (Fig. 4).

To test whether T11A9e antibody recognizes intermediate filaments through its Fc segment, the T11A9e antibody was preincubated for 30 min at room temperature with various concentrations of Thy-1.1 purified from rat brain (provided by I. Trowbridge). The mixture was then used to stain either Thy-1 at the surface of unfixed F2408 cells, or intermediate filaments in acetone-treated F2408 cells. Thy-1 at a concentration of 30 μg ml $^{-1}$ completely inhibited both types of staining. The Thy-1 concentrations at which the proportion of surface-stained cells or the intensity of filament staining (as judged from visual observation) was reduced to 50% were similar, $\sim 1~\mu g$ ml $^{-1}$. Therefore both target molecules are recognized by the same antibody site.

In addition to T11A9e, two out of 13 monoclonal anti-Thy-1 antibodies also stain intermediate filaments; these are T12G11c

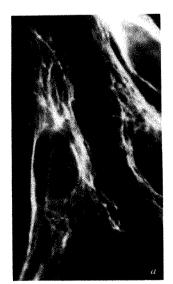

Fig. 3 Double immunofluorescence of F2408 cells with T11A9e and anti-vimentin serum. Immunofluorescence was carried out as described for Fig. 1b. a, The first antibody was a rabbit anti-vimentin serum and the second antibody was rhodamine-conjugated goat anti-rabbit immunoglobulin. b, The first antibody was T11A9e serum and the second, fluorescein-conjugated goat antimouse immunoglobulin. Photographs were taken using the appropriate filters for detection of fluorescence by rhodamine (a) or fluorescein (b). \times 1,400.

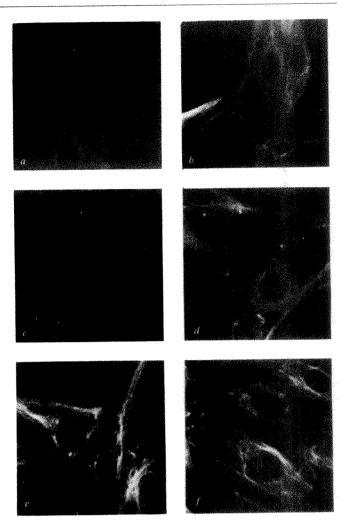

Fig. 4 Absorption of T11A9e serum with Thy-1-positive cells and their negative mutants. $100~\mu l$ of serum diluted 1/100 in PBS were absorbed in each case with $5\times10^8-5\times10^9$ cells of various mouse thymoma lines 12 (provided by R. Hyman). After 1 h at room temperature with frequent shaking the mixtures were centrifuged at 2,000 r.p.m. for 10 min. The supernatants were used in immunofluorescence experiments with F2408 cells as described for Fig. 1b. Absorbing cells: a, BW5147.3 · Thy-1.1 · ; b, BW5147.3 · Thy-1.1 · ; c, BW5147 · Thy-1.1 · ; d, BW 5147 · Thy-1.1 · ; e, S49 · Thy 1.2 · ; f, S49 · Thy 1.2 · a. The fields were photographed and printed using identical exposures. $\times 800$.

(IgM) and T32B11e (IgG) (both from P. Lake and E. Clark). The others give only a faint uniform fluorescence, probably due to surface Thy-1. Of the positive antibodies, T12G11c may be from the same lymphocyte clone as T11A9e, but T32B11e is likely to be different. Two conventional anti-Thy-1 rabbit antisera, obtained using purified Thy-1 from rat brain or from mouse thymocytes, did not stain the filaments.

To identify the protein to which the T11A9e antibody binds in the intermediate filaments, cytoskeleton proteins of F2408 cells were isolated as previously described¹², labelled with ¹²⁵I then immunoprecipitated with T11A9e antiserum, using a second antibody. Separation by polyacrylamide gel electrophoresis and autoradiography did not reveal any band of precipitated material. This antibody also fails to precipitate surface Thy-1. These failures may reflect a low affinity of the antibody. In spite of the lack of immunoprecipitation it is likely that T11A9e antibodies bind to vimentin because the T11A9e immunofluorescence of intermediate filaments is suppressed by anti-vimentin antiserum.

Because serum from mice inoculated with another isolate of the same hybridoma (T11A9a, no longer available) had a strong in vitro anti-doming effect on mammary cells¹³, we examined the possible relationship of this effect with our results. We found that the anti-doming effect was not removed by absorption to Thy-1.1-positive cells and was therefore unrelated.

We do not know whether the cross-reactivity we have observed is due to the proteins or possibly to some common carbohydrate. If the former is correct, it might reveal either a relatedness of the two proteins or a chance similarity of antigenic sites. In the latter case, our observation would be an example of the cross-reactivity of monoclonal antibodies predictable on theoretical grounds². The frequency of cross-reacting antibodies is unknown. When mice and rats were immunized with Thy-1, antibodies showing the cross-reaction we described occurred in 3 out of 13 monoclonal antibodies examined, but may not represent the true proportion because two of the antibodies may have a common origin. No general statement about the frequency of cross-reactivities can be made on the basis of these results or of past experience with immune sera. This remains to be established in further experiments using monoclonal anti-

We thank Drs I. S. Trowbridge and R. Hyman for advice, Drs P. Lake, E. Clark, I. S. Trowbridge, A. Williams and E. Weissman for supplying monoclonal antibodies, and J. Singer for the antivimentin antiserum. Enzymatic synthesis of deshexapeptide insulin

Q. P. Cao, D. F. Cui & Y. S. Zhang

Shanghai Institute of Biochemistry, Chinese Academy of Sciences, 320 Yueyang Road, Shanghai, China

The semisynthesis of deshexapeptide insulin (DHI) from desoctapeptide insulin (DOI) reported earlier1 showed that DHI was biologically active. However, the product was not quite homogeneous, mainly due to the esterification side reaction and the following saponification². Recently, the catalytic action of trypsin was successfully used in the preparation of human insulin from porcine insulin3. It was also used in the preparation of insulin analogues with substitutions of B24 or B25 phenylalanine by leucine^{4,5}. Here, we report the synthesis of DHI from DOI and glycylphenylalanine through the catalytic action of trypsin. The product, purified by gel filtration and DEAE-Sephadex ion-exchange chromatography, showed insulin activity of 7.5 IU mg-1 in vivo and could be obtained in crystalline form.

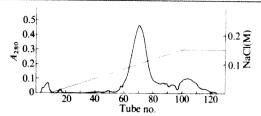

Fig. 1 Isolation of DHIOBu' from DOI by ion-exchange chromatography on a DEAE-Sephadex A-25 column (1×25 cm). 50 mg of sample were applied to the column, eluted using 50 ml of the initial 0.05 M Tris buffer, pH 7.6, with 40% isopropanol and then eluted through a salt gradient (from 200 ml of initial buffer containing 0.15 M NaCl to 200 ml of initial buffer alone). The eluent was collected in ~4-ml fractions. Active fractions were pooled, desalted by dialysis and lyophilized. The main peak is DHIOBu and the last peak, DOI.

The conditions for the enzymatic synthesis of DHI were different in certain aspects from those reported by Inouye et al.3. The alkali-labile methylsulphonylethoxycarbonyl group (Msc) was used⁶ instead of the t-butyloxycarbonyl group (Boc). The t-butyl ester (OBu') was not affected by the removal of Msc⁶, and DHIOBu' had one less negative charge than DOI; thus, they could be easily separated from each other by ion-exchange chromatography.

120 mg of (Msc)₂DOI and Gly-Phe-OBu' in excess (molar ratio = 1:60) were suspended in 0.16 ml of dimethyl sulphoxide (DMSO) and 1.08 ml of dimethylformamide (DMF) were added to ensure complete solubility. The solution was warmed to 37 °C and 0.96 ml 0.5 M Tris buffer, pH 8, added dropwise and the pH maintained at 7.8-8.0 by continual addition of triethylamine. Crystalline ovine trypsin was added and the solution incubated at 37 °C for 20 h. The total amount of enzyme used (12 mg) was added in three portions: at the start and after 2 and 6 h of incubation. At the end of the incubation, 40 ml of water were added and the pH adjusted to 4.2 using 1 M HCl. After cooling, the precipitate was collected by centrifugation, washed in water (pH 4.2) and lyophilized; 95.5 mg of dry powder were obtained. This powder was suspended in 4.78 ml of a solvent mixture, dioxane-methanol-water (3:0.5:3.5) and dissolved by adding a small amount of 2 M NaOH. The solution was cooled to 0 °C and 2 M NaOH at 0 °C added until the total amount was 0.68 ml. The deblocking reaction was carried out at 0 °C for 2 min and immediately stopped by the addition of acetic acid. The solution was then applied to a Sephadex G-50 column and eluted with 1 M acetic acid to remove high-molecular weight polymers. DHIOBu' and DOI were separated by DEAE-Sephadex chromatography (see Fig. 1). The purified DHIOBu'

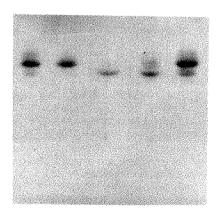

Fig. 2 Polyacrylamide gel electrophoresis of, from left to right: crude DHIOBu', purified DHIOBu', purified DHI, DOI and crude DHIOBu'; the lower end is the anode.

was treated with trifluoroacetic acid (TFA, 2.5 mg ml⁻¹) at 0 °C for 1 h. TFA was then removed by evacuation and the residue washed twice with ethyl acetate. 10 mg of the product were further purified by DEAE-Sephadex A-25 chromatography to remove any unreacted DHIOBu' and 7 mg of purified DHI were obtained. The purified DHI was dissolved in 0.01 M HCl (1.5 mg ml⁻¹) and dialysed against citrate buffer containing 25% acetone (2% citric acid, 50 ml; 6.5% zinc acetate, 1 ml; acetone, 25 ml; adjusted to pH 5.7-5.8 with NaOH and diluted to 100 ml). DHI crystals appeared after standing overnight.

The biological activity of purified DHI was determined in a mouse convulsion assay (according to British Pharmacopoeia) as 7.5 IU mg⁻¹. DHIOBu' also possessed insulin activity, thus it was easily detected and collected by DEAE-Sephadex chromatography. However, its activity is about four times lower than that of DHI. The activity of DOI is less than 1% compared with insulin.

After DEAE-Sephadex chromatography (Fig. 1), the DHIOBu' peak yielded 29.8 mg and the DOI peak, 4.9 mg; a ratio of 86:14. Polyacrylamide gel electrophoresis7 showed that

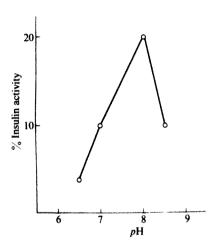

Fig. 3 The optimum pH for the enzymatic synthesis of DHI from (Boc)2 DOI and Gly-Phe-OBut.

most of the DOI was converted into DHIOBu' (Fig. 2). DOI moved faster towards the anode than DHIOBu'. When OBu' was removed, DHI occupied the same position as that of DOI. Purified DHI gave one major band after electrophoresis. Its amino acid composition was determined as: His, 2.4 (2); Arg, 0.9 (1); Asx, 3.0 (3); Glx, 6.3 (7); Thr, 1.1 (1); Ser, 2.7 (3); Gly, 3.8 (4); Ala, 1.1 (1); Val, 3.4 (4); Ile, 1.7 (2); Leu, 5.1 (6); Tyr, 2.6 (3); Phe, $1.9 (2) (Cys)_2$ not determined.

In enzymatic synthesis, co-solvent must be used—we used Tris buffer containing 50-60% DMF with a small amount of DMSO to increase the solubility. In tryptic hydrolysis, the optimal pH was found to be around 8 (Fig. 3). Inouye et al.3 used a pH of 6.5 for their synthesis. We have compared the enzymatic synthesis of DHI from (Boc)2DOI and Gly-Phe-OBu' in solutions of different pH, and found that the optimum pH was 8. The yield of the enzymatic reaction of (Msc)₂DOI and Gly-Phe-OBu' was 74%, calculated from the amount of DHIOBu' and DOI obtained by DEAE-Sephadex chromatography and the small portion of DOI polymers in gel filtration. This result could be attributed to several factors: (1) An increase in the equilibrium constant of synthesis due to the presence of co-solvent, which decreases the equilibrium constant of proton transfer from the carboxyl to the amino group of the reactants, as reported by Homandberg et al.8. (2) The high concentration of reactants and the large excess of Gly-Phe-OBu' drive the reaction towards synthesis according to the law of mass action. (3) The pH (8) was optimal for the catalytic action of trypsin. (4) Both reactants are very soluble at this pH.

We thank Dr D. Saunders for supplying Msc N-hydroxysuccinimide.

Comparative antiviral efficiency of leukocyte and bacterially produced human α -interferon in rhesus monkeys

Interferons are being tested as antiviral and antitumour agents in man1-5, but because of their limited availability, clinical trials have remained inconclusive. Most of the interferon (IFN) preparations tested in man have been derived from human peripheral blood, buffy-coat leukocytes (HuIFN- α)⁶ induced by Sendai virus or from human diploid fibroblastoid cells (HuIFNβ) superinduced with poly(rI)-poly(rC)7. As production of interferon from leukocytes is restricted by the availability of blood donors, and production from cultured cells is a laborious and relatively costly process, the use of recombinant DNA technology may provide the most economical approach to the large-scale production of pure species of human interferon. The testing of such interferons is in its infancy. With the availability of bacterially produced HuIFN-a2 we have been able to compare its activity against vaccinia virus infection of the rhesus monkey with that of HuIFN-α from leukocyte buffy coats. Here we provide evidence that the two human α -interferons have comparable antiviral activity but that the bacterially produced form has fewer side effects, at least in the rhesus monkey.

There have been reports of the isolation of cDNAs encoding different HuIFN-a species, and of the production of polypeptides with the antigenic and biological properties in vitro of interferon from Escherichia coli harbouring appropriate hybrid plasmids⁸⁻¹⁰. An important question is whether interferons produced by E. coli have the same efficacy in vivo as natural interferons. The polypeptides produced in E. coli may differ from those produced in leukocytes due to postsynthetic modifications such as proteolytic cleavage, acylation or glycosylation. Recent evidence suggests that, contrary to previous indications, most if not all HuIFN-α species from leukocytes or lymphoblastoid cells are not glycosylated11, therefore, at least in this regard, we expect interferons made in E. coli to be no different. In addition, HuIFN-α from buffy coats is a mixture of several distinct species11,12 which are encoded by different genes¹³. The different IFN- α species differ substantially in their amino acid sequences (refs 10, 14, 15 and K. Henco, J. Fujisawa and J. Schmid, unpublished results) and in some of their biological activities, determined in vitro 14. In view of these considerations, the effect in vivo of a single species of α -interferon produced in E. coli may differ from that of a preparation of natural α -interferon. One report has described the protection of squirrel monkeys against a lethal dose of encephalomyocarditis by both natural HuIFN- α and a HuIFN- α from E. $coli^{10}$; in this experiment only one very high dosage of the interferons was tested, thus no conclusions could be drawn regarding their relative effectiveness.

There have been reports of rhesus monkeys infected intradermally with vaccinia virus to test the antiviral activity of human interferon¹⁶⁻¹⁸. The parameters influencing the activities of human interferon in vivo were extensively tested in this model system. The pharmacokinetics and the sensitivity of the rhesus monkey to the antiviral activity and side effects of human interferons were similar to those of man. Suboptimal doses of interferon can also be tested in this model.

We have compared the antiviral effects of different doses of HuIFN- α from buffy coats with HuIFN- α from E. coli in our rhesus monkey vaccinia model and studied the possible side effects of these products. The natural HuIFN- α , prepared as previously described⁶, had a specific activity of $10^{6.2}$ U per mg. HuIFN- α_2 was expressed in E. coli from an IFN- α_2 cDNA from which the signal sequence 14 had been removed and replaced by a methionine codon (M. Mishina, W. Boll and A. Hall, unpublished results). Purification of interferon from E. coli extracts involved acid precipitation, chromatography on agarose-linked Cibacrone blue and reversed-phase HPLC; the final product had a specific activity of 10^{7.6} U per mg protein and showed a single major interferon band and one minor band on SDSpolyacrylamide gel electrophoresis.

Three doses of each interferon (50,000, 150,000 and 500,000 U per kg body weight) were administered to groups of three monkeys each, by daily intramuscular injections, starting the day before challenge with vaccinia and continuing for 7 days after challenge. Three hours after the second interferon treatment the levels of circulating interferon were similar for both types, at all dosage levels (Table 1). All three dosages of natural and bacterial interferon had significant antiviral activity and the degree of protection was dose dependent (Table 1). The highest doses used completely abolished vaccinia-specific lesions. The in vivo antiviral activities of the two preparations were similar to their activities in vitro. The side effects of the two interferons. however, differed significantly (Table 2). Natural α -interferon from buffy coats, at a dose of 500,000 U per kg, caused leukopenia and fever, whereas the interferon from E. coli did not. Liver and kidney function tests showed no adverse effects of either type of interferon. Subsequently, doses of 10⁷ U E. coli

Table 1 Comparison of the efficacy of natural HuIFN-α (buffy coat) and HuIFN- α_2 (E. coli) in vaccinia-infected rhesus monkeys

Dose	Circulating	Circulating interferon		Lesion score (day 7)		
(U per kg body weight)	HuIFN-α (buffy coat)	HuIFN-α ₂ (E. coli)	HuIFN-α (buffy coat)	HuIFN-α ₂ (E. coli)		
500,000	480 (±0)	380 (±92)	$0.7*(\pm0.8)$	1.2* (±1.0)		
150,000	$80 (\pm 35)$	$120(\pm 43)$	$1.5*(\pm0.5)$	1.5* (±0.5		
50,000	40 (±17)	73 (±42)	2.2* (±0.8)	2.4* (±1.2		
Untreated cor	ntrols	<20	4.0 (0.0)			

Rhesus monkeys (Macaca mulatta; bred at the Primate Centre, The Netherlands) weighing 1.5-2 kg were used. Natural HuIFN- α was induced in buffy coats using Sendai virus and purified to the stage PIF-1 (see ref. 6); the specific activity was 10^{6.2} U per mg protein. HuIFN-α₂ (E. coli) was prepared from E. coli trans formed by the plasmid Z-pBR(Δ Ampi)/IFN- α_2 (Δ sig)-M2lb (M. Mishina, W. Boll and A. Hall, unpublished results) and had a specific activity of $10^{7.6}$ U per mg protein. The monkeys were injected intramuscularly with the doses indicated from day -1 until day +7. Each treated group consisted of three monkeys. Four untreated monkeys served as controls. On day 0, the animals were sedated with ketamine hydrochloride, blood was taken and all monkeys were vaccinated with vaccinia virus (Elstree strain, 10^8 plaque-forming units per ml) using a Sterneedle device. At day +7, the skin lesions were scored according to an arbitrary scale16 from 0 to 4 based on the appearance of papules and pustules, and severity. Results are the mean ±s.d. Interferon activity was assayed using cytopathic inhibition effect test on WISH cells.

Significant protection at the P < 0.01 level when compared with untreated controls in the Mann-Whitney U-test. A score of 0.5-1.0 is equivalent to the response found after injection of 0.9% NaCl (refs 16, 17).

Table 2 Comparison of the side effects of HuIFN- α (buffy coat) and HuIFN- α_2

	Leukocyte c	Temperature °C	
	Day -2	Day 0, 3 h after interferon	(Day 0, 3 h after interferon)
Natural HuIFN-α (buffy coat) (500,000 U per kg body weight)	14.1 (±3.6)	7.2* (±1.3)	38.1† (±1,5)
Bacterial HuIFN-α ₂ (500,000 U per kg body weight) Untreated controls	12.6 (±2.7) 15.7 (±4.8)	15.0 (±3.1) 14.0 (±4.1)	36.3 (±0.6) 36.7 (±0.4)

For experimental details see Table 1 legend. On day -2 and day 0 (3 h after interferon administration), the animals were sedated using ketamine hydrochloride and blood was taken for routine blood chemistry and haematology. At day 0, the body temperature was measured rectally and the monkeys were vaccinated (see Table 1 legend). Values are mean leukocyte counts and temperature ±s.d. Significant reduction (P < 0.05) when compared with day -2 in the Mann-Whitney U-test.

Significant temperature rise at a P = 0.053 level when compared with untreated controls and P < 0.05 when compared with the animals treated with HuIFN-α2 (E. coli).

IFN α_2 per kg were administered to three monkeys, again without giving rise to fever, leukopenia, anaphylactic reactions or other evidence of toxicity. The difference in toxic effects between the two interferon preparations when administered to rhesus monkeys could be due to the higher degree of purity of the bacterial product. However, recent work by Scott et al. 19 shows that even highly purified leukocyte interferon (NK2-IF), prepared using antibody affinity chromatography, shows the same toxic effect as the much less pure PIF preparation. Perhaps the toxic effects are due to one or more of the α -interferon species other than IFN- α_2 , present in the preparation derived from buffy coats. Alternatively, as Genentech's α -interferon (type A, which is equivalent to our α_2) purified from E. coli apparently still causes fever and leukopenia in humans (see Nature 291, 105–106; 1981), it could be that the rhesus monkey is not sensitive to the pyrogenic activity of pure α -interferon, and the response we found with the natural interferon was due to impurities in that preparation.

Our study illustrates the use of the vaccinia-infected rhesus monkey as a model for comparing the effects of different interferon preparations. We show that an interferon species produced by recombinant DNA techniques has the same antiviral efficacy in vivo as a natural interferon preparation. If the lack of side effects demonstrated in the rhesus monkey proves to be the same for humans, it may be possible to increase the dosage by one order of magnitude or more over that now used.

We thank Dr Kari Cantell for his gift of buffy-coat HuIFN-α and Miss Ellen de Vreede and Mr Hilko D. Wiersema and his assistants for technical assistance. The work at the University of Zürich was supported by the Kanton of Zürich and by a grant from Biogen.

Interaction of the antihypertensive drug felodipine with calmodulin

Stig-Lennart Boström*, Bengt Ljung*, Sven Mårdh†, Sture Forsen‡ & Eva Thulin‡

* AB Hässle Research Laboratories, S-431 83 Mölndal, Sweden and Department of Physiology, University of Göteborg, Sweden † Institute of Medical and Physiological Chemistry, Biomedical Center, Box 575, Uppsala University, S-751 23 Uppsala, Sweden ‡ Physical Chemistry 2, Chemical Center, POB 740, S-220 07 Lund, Sweden

Despite the marked differences in their chemical structure, members of a heterogeneous group of pharmacological agents are thought specifically to block Ca2+ influx through calcium channels and thus mediate negative inotropic cardiac effects and vasodilatation. Electrophysiological studies of the myocardium have shown that the slow inward Ca2+ current is blocked1, but the cellular mechanism of these agents in vascular smooth muscle is largely unknown. Felodipine [4-(2,3-dichlorophenyl)-1,4-dihydropyridine-2,6-dimethyl 3,5-dicarboxylic 3-ethylester and 5-methylester)] is a new antihypertensive agent which seems specifically to dilate precapillary resistance vessels in vivo. It is a structural analogue of nifedipine and SKF 242602, both of which have been classified as 'calcium antagonists', implying that their vascular as well as myocardial actions are due to a blockade of Ca2+ influx. However, the findings reported here point rather to an interaction between felodipine and calcium-binding proteins such as calmodulin.

The effects of felodipine were studied in the isolated rat portal vein. The smooth muscle of this vessel shows many similarities to that of the haemodynamically important small resistance vessels, including its pronounced dependence on extracellular $[Ca^{2+}]$ (refs 3-5). Figure 1a shows the spontaneous phasic electrical and mechanical activity of the rat portal vein in the absence of inhibitors. The addition of felodipine (30 nM) produced a gradual decrease of integrated electrical membrane discharge and reduced the amplitude and duration of the contractions (Fig. 1c, d), whereas tetrodotoxin, at a dose level capable of blocking sodium channels, did not affect this spontaneous activity (Fig. 1b).

Figure 2 shows the dose response of the portal vein to cumulative doses of CaCl₂ in a K⁺-rich solution. The presence of felodipine at low concentration (0.1 pM) in a Ca²⁺-free solution for 1 h markedly depressed the contractile responses when Ca²⁺ was reintroduced (Fig. 2).

Similar experiments investigated transmembrane Ca^{2+} influx in K^+ -depolarized muscle. The Ca^{2+} -depleted portal veins were

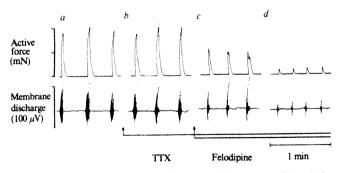

Fig. 1 Effects of felodipine (30 nM) on extracellularly recorded electrical membrane discharge and contractile force of the spontaneously active smooth muscle of the rat portal vein. Vessel mounted for recording of activity in longitudinal media layer²⁰. Intermittent bursts of electrical membrane discharge and associated phasic contracting are seen in the control (a). Administration of tetrodotoxin (TTX, 1 µM; b) in a concentration which would abolish neurogenic vasoconstrictor responses²¹, reflecting blockade of Na* channels, did not affect the activity. However, addition of felodipine (30 nM) led to a gradual inhibition of membrane discharge and of mechanical force illustrated 20 min (c) and 40 min (d) after administration.

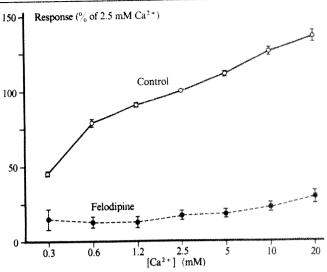

Fig. 2 Effects of felodipine (0.1 pM) on isometric force development in response to graded concentrations of Ca²⁺ in isolated rat portal vein lying in high-K⁺ (128 mM) Tris-buffered Krebs solution. Ca²⁺ added to solution after 1 h incubation in nominally Ca²⁺-free Krebs ('Control') and after a subsequent 1 h in Ca²⁺-free solution containing the drug. All responses expressed as a percentage of the initial response to 2.5 mM Ca²⁺. Values obtained in the presence of felodipine were corrected for the decline observed in control experiments where no drug was added (mean±s.e., n = 8). Note the pronounced felodipine blockade of Ca²⁺ responses in the depolarized vascular smooth muscle.

'pulse-labelled' with 45Ca²+ in 1.2 mM CaCl₂ for 2 min, sufficient time for a contracture to develop. The tissues were then washed in a Ca²+-free lanthanum buffer for 1 h to displace extracellularly bound Ca²+. As Fig. 3 shows, the 45Ca²+ uptake was identical after 1 h incubation with or without 1 nM felodipine. However, after treatment with 2 mM LaCl₃ for 1 h, the cellular 45Ca²+ uptake was <10% of control (Fig. 3). In agreement with these results, Church and Zsoter were unable to detect any alteration in 45Ca²+ uptake on treatment with nifedipine, verapamil or diltiazem in concentrations producing a clear-cut inhibition of smooth muscle activity. It thus seems that felodipine and some other calcium antagonists interfere with intracellular Ca²+ utilization rather than with transmembrane Ca²+ influx during activation.

To explore possible interactions between felodipine and myofibrillar proteins, 14 C-felodipine was incubated for 1 h with a Ca^{2+} -sensitive crude actomyosin preparation from porcine aorta⁸; samples were then subjected to SDS-polyacrylamide gel electrophoresis. One gel was stained for protein with Coomassie brilliant blue and in the other the distribution of radioactivity was measured in 5-mm sections of the gel. Molecular weight (M_r) estimations were made with standard proteins. Radioactivity was detected only at the dye front and in the 15,000–20,000 M_r region.

Calmodulin $(M_r 16,700)$ occurs in the cytoplasm and is bound to a membrane fraction⁹ and to other proteins¹⁰; its interaction with a drug could therefore affect smooth muscle activity¹¹⁻¹³. When ¹⁴C-felodipine was incubated with calmodulin and subjected to electrophoresis, the radioactivity in the gel was found to coincide with the site of protein staining.

On binding calcium, calmodulin is converted from an inactive to an active form which may influence various cellular processes $^{14.15}$, possibly also membrane activation 16 . Apparently, calmodulin can bind a maximum of 4 mol Ca^{2+} per mol protein when assayed at high ionic strength $^{14.15}$. Potentiometric titration of smooth muscle calmodulin with $CaCl_2$ [in 20 mM imidazole buffer (pH 7.0, 22 ± 1 °C) with 100 mM KCl] resulted in an equivalence point corresponding to an uptake of 4 mol Ca^{2+} per mol protein, as determined using the Gran-plot technique 17 . However, in a concentration of 4 mol felodipine per mol of protein, the binding was reduced to ~ 2 mel Ca^{2+} .

In NMR studies, ¹¹³Cd has a spin I = 1/2 magnetic nucleus and the similarity of the ionic radii of Cd (0.0097 nm) and Ca²⁺

(0.0099 nm) makes Cd2+ a good substitute for Ca2+ in Ca2+ binding protein18. The addition of felodipine to (Cd)4-calmodulin produced dramatic changes in the 113 Cd-NMR spectrum (Fig. 4), which can be taken to indicate that the binding of felodipine to calmodulin causes the conformation of the latter to change in such a way that at least one of the Ca2+-binding sites is altered. This interaction is apparent at a molar ratio of felodipine to calmodulin of only 0.5: 1. The ¹¹³Cd-NMR results obtained also show that 1-2 mol felodipine are bound per mol calmodulin with a binding constant of $10^5 - 10^6 \,\text{mol}^{-1}$.

Trifluoroperazine, which is known to interact with calmodulin did not inhibit smooth muscle in the rat portal vein (results not shown). Furthermore, their different 113Cd-NMR spectra 18 indicate that the conformational change of calmodulin induced by trifluoroperazine is qualitatively different from that caused by felodipine.

Overall, these results indicate that felodipine may exert its vasodilator effects by interacting with a Ca2+-binding protein rather than by inhibiting Ca2+ influx. Church and Zsoter7 have recently shown that nifedipine and other so-called Ca24 antagonists do not impair transmembrane Ca2+ transport in either vascular or cardiac tissue. Furthermore, it is debatable whether Ca2+ antagonists do indeed act by selective inhibition of slow Ca²⁺ channels in the myocardium¹⁹. We suggest that felodipine and possibly other Ca2+ antagonists exert at least some of their effects by an action on calmodulin or other Ca²⁺-binding proteins.

This work was supported in part by grant 3884 from the Swedish MRC.

45Ca2+ uptake (c.p.m. per mg dry weight)

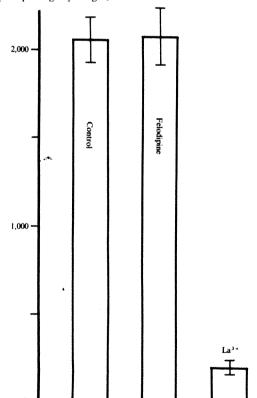

Fig. 3 Effect of felodipine and lanthanum (La3+) on 45Ca2+ influx in the rat portal vein. After an initial period of 1 h in Tris-buffered Krebs solution, the muscles were kept for 1 h in a Ca²⁺-free solution. The tissues were then transferred to a high-K⁺ (128 mM), Ca²⁺-free Tris-buffered solution for 10 min. The muscles were then pulse-labelled⁶ with ⁴⁵Ca²⁺ for 2 min using 45Ca²⁺ in 1.2 mM CaCl₂ in the high-K⁺ buffer. During such a 2-min CaCl₂ exposure a contracture developed in the control specimen. After the initial period experimental muscles were exposed to felodipine (1 nM) or La3+ (2 mM). After the 2-min labelling period, the muscles were washed for 1 h in nominally Ca2+-free Tris-Krebs solution including 2 mM LaCl2. The muscles were then blotted lightly, dried overnight at 100 °C, weighed, dissolved and analysed for 45Ca.

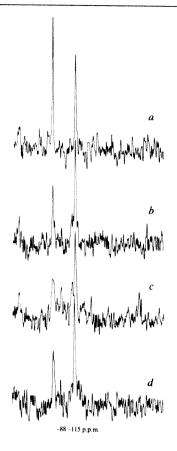

Fig. 4 The effects of felodipine on the 113Cd-NMR spectrum of a 1 mM solution of (Cd)₄-calmodulin (bovine testes) at pH 8.4 (Tris-perchlorate buffer). In the absence of felodipine (a) the two 113Cd-NMR signals are observed at -88 and -115 p.p.m., respectively, relative to 0.05 m Cd(ClO₄)₂; higher fields have negative shifts. The molar ratio of felodipine to calmodulin is: b, 0.6: 1; c, 0.9: 1, d, 2.0: 1. The felodipine was added as a 10 mM solution in ethanol-cremaphor RH410 (9:1). Apart from a small change in chemical shift of signal at -88 p.p.m. (~2 p.p.m. towards higher fields, the effects of the felodipine solvent corrected for), a broadening of both 113Cd-NMR signals is observed. The broadening which is most marked on the signal at -88 p.p.m. has its maximum at a molar ratio of felodipine to calmodulin of ~1:1. Further addition of felodipine causes the signals to become narrower again. The observed effect of felodipine on the ¹¹³Cd-NMR spectra of (CD)₄-calmodulin is similar to the effect observed on the addition of 1 mol of trifluoperazine per mol calmodulin. The 113Cd-NMR spectra were obtained at 55.54 MHz on a 6.0 T FT NMR spectrometer. The sample volume was 2.5 ml and the sample was placed in a solenoid perpendicular to the axis of the superconducting magnet. Each spectrum is the result of 25,000 transients obtained during 4 h. The sample temperature was 23 ± 1 °C.

TERS ARISING

Disruption of meteoritic iron parent bodies

THE discovery by Clarke et al.1 of preterrestrial shock polymorphism (& structure) and shock-induced diamond in Allan Hills A77283 has implications for the process by which the parent body of this meteorite disrupted.

The internal metallographic structures of meteoritic iron seem to require well insulated parent bodies of 10-100 km size^{2,3}, whereas iron meteorites typically fall to Earth as bodies of 10-100 cm with occasional crater-forming masses of perhaps up to 100 m size. However, of the 70 or so IA irons (excluding A77283) only 3 show sufficient signs of mechanical damage to produce the ε structure⁴. Of these three Cañon Diablo is well known to contain diamond, but is a crater-forming mass and the indications are that its shock effects arose during Earth impact. Cranbourne and Magura are showers, not associated with known craters, and are badly corroded. Magura has been reported to contain diamond4.

In the absence of ablative heat effects it is difficult to say whether the shock effects in Cranbourne and Magura are pre-terrestrial or not, but the Allan Hills A77283 observations now open up the possibility that they may be.

Thus, the disruption of the IAB parent body seems to have been effected with major damage (ε) to only two or three of the resulting fragments. By contrast, most of the 130 or so members of the IIIAB group show ε structures or shock heating effects.

It is therefore easy to accept a collision process for the disruption of the IIIAB parent body but the marked absence of shock polymorphism in the IAB irons is puzzling. One possibility is that the distribution of non-metal phases (silicates, sulphides) was different in the two parent bodies and allowed damage to be more concentrated in the non-metal portion of the IAB parent. The new evidence on A77283 and the possible pre-terrestrial character of shock effects in Cranbourne and/or Magura now indicate that collision was involved in the disruption of the IAB parent body. The nature of the assumed non-metal portion of the IAB parent which bore the brunt of collision damage remains unresolved but the position of the shocked diamondiferous ureilites might be reconsidered in this context.

Fish versus zooplankton predation in lakes

FISH predation has traditionally been viewed as one of the most important factors regulating zooplankton community structure in freshwater lakes 1,2 Recently Lane³, approaching the problem from a different point of view, has conducted comparative studies of vertebrate and invertebrate predation in a temperature freshwater lake numerous species of zooplanktivorous fish and concluded that piscine predators "probably have little effect on the myriad of interactions among most zooplankton species". Lane's comparative approach for studying predation in aquatic systems is commendable. However, we question her conclusion that fish were unimportant in affecting the zooplankton community which she studied because the following methodological problems of her work would result in a gross underestimate of the relative impact of fishes.

(1) Fish biomasses were poorly estimated. Estimates of absolute densities of fish cannot be made with gill nets unless ancillary studies are conducted (that is, mark and recapture). Additionally, gill nets are not available in mesh sizes which will catch larval and small juvenile fish. Consequently, Lane's estimates of fish density ignored juveniles of the 70 fish species in the lake. Most juvenile fish are planktivorous4, and although small, are more abundant than large fish; their relative consumption rates are also greater⁵. Therefore, they may significantly affect total piscine predation rates. Only predation by one fish, Osmerus mordax, was considered in her study. Consumption by other species was ignored because they were seldom caught in gill nets or were considered "inshore species". However, gill nets are highly selective for some species⁶, and absence from these nets does not indicate absence from a system. Inshore species may also have access to pelagic plankton by undertaking diel migrations to the pelagic zone^{7,8} or by locating plankton concentrated near the littoral by currents9. We have observed both types of behaviour in a zooplanktivorous fish, Menidia audens (W.W. and H.L., unpublished results).

(2) Prey consumption rates by fish were severely underestimated. Samples to estimate gut fullness and evacuation rates were taken at only three periods during 24th cycles: significantly, none was taken during daylight periods. Consequently, feeding peaks may well have been missed. For example, our work with Menidia indicates that dawn and dusk feeding peaks would be largely missed with Lane's sampling regime and would result in an underestimate of consumption rates by at least 100%. Lane's data suggest that at least some feeding by Osmerus occurs during daylight, as on one of three sample dates, fish were 60% full at sunset. She also assumed a linear instead of an exponential model of gut evacuation and that feeding and gut evacuation are mutually exclusive events. These assumptions, coupled with infrequent sampling, can also lead to severe underestimates of consumption rates10

(3) Additionally, there are apparent difficulties in estimating invertebrate predation rates. Lane's previously published estimates of zooplankton predation rates 11,12 differ by more than one order of magnitude. Such differences could lead to considerable errors in interpreting the relative importance of vertebrate and invertebrate predation. We also question the statement that "Cyclops . . . perhaps selects prey more for their availability than for any other factor",3 because prey morphology, size and behaviour contribute significantly to prey selection 13-15.

Lane's work has shown that invertebrate predators must exert an important evolutionary pressure on zooplankton community structure. Additionally, she has emphasized that the effects of fish on he often the zooplankton may indirect 14,16. However, given methodological difficulties listed above, we are unconvinced that fish have little effect, whether direct or indirect, on zooplankton communities.

LANE REPLIES—Wurtsbaugh et al. state that I concluded fish to be unimportant with regard to zooplankton community structure¹. I did not draw this conclusion. They confuse two questions: (1) Which predators, vertebrate or invertebrate. exert the most predation pressure on lake zooplankton?, and (2) what is the significance (importance) of these predation pressures? My paper was concerned with providing a quantitative answer for question (1). With regard to question (2) I was careful not to make value judgements. I stated that vertebrate predators often "dramatic effects" have on lake zooplankton. I shall reply to the three methodological criticisms of Wurtsbaugh et al., then clarify the problem of significance (silver bullet obsession).

(1) Fish density: my report gave only a small part of a 4-yr collection effort of the Gull Lake fish community. In addition to gill nets, mark and recapture, a high-speed sampler, a purse seine, sonar, dip nets and hand lines were used for field sampling, and experimental cages were used for predation studies on immature fish. We did not have access to a midwater trawl which has been successfully used in the Great Lakes². Our laboratory studies showed that clipped smelt were highly susceptible to fungus infections and exhibited high mortalities. Others have found summer marking to be impractical³. Consequently, we abandoned this method of estimating fish populations. As Wurtsbaugh et al. point out, most types of fishing gear are selective4; however, sonar traces gave reasonable agreement with gill-net results.

They are correct in stating that juvenile fish "may affect significantly total piscine predation rates" for some environments and there is undoubtedly some error there. Their argument for designating juvenile fish as important predators was based on the reasoning that they are more numerous and have greater relative consumption rates than adults. When I used a similar argument in comparing vertebrate with invertebrate predators, Wurtsbaugh et al. failed to acknowledge it. The reasoning is correct for both arguments, if smaller predators are more numerous. The combined sampling

methods failed to reveal large numbers of immature fish occupying the central station. References to littoral Menidia audens, the Mississippi silverside, which inhabits shallow, warm Clear Lake, California, are irrelevant to the Gull Lake situation for almost all comparable criteria⁵⁻¹⁵. My study¹ was restricted to the pelagic zone.

Fish consumption rates: all diurnal sampling was done with four periods as Table 1 of my paper clearly shows. Use of sonar to check the absence of fish during the day and their diurnal movements were mentioned in Fig. 1 legend. In a subsequent study, smelt were collected on transects from the central station to shore. Data on their stomach contents provided no evidence of inshore feeding during the day or of a dawn feeding peak. Wurtsbaugh et al. make two useful points about linear compared with exponential models of gut evacuation and the assumption of independence of feeding and gut evacuation. Usually gut evacuation time and feeding periodicity are determined experimentally. The smelt did not cooperate in our laboratory studies thus I kept the model as simple as possible.

Invertebrate predation rates: these do differ by an order of magnitude over the large range of conditions in my experiments. Feeding rates for filter-feeding zooplankton are also as variable; density relationships are even more variable. Environmental heterogeneity and feeding periodicity also contribute to rate variations. I stated in Fig. 1 legend1 that many other invertebrate predators consume the prey species; this would underestimate the degree of invertebrate predation extant in Gull Lake^{16,17}

(2) Significance: I concluded that smelt account for $\sim 5\%$ of the total predation on Gull Lake zooplankton¹. This does not mean that invertebrate predators are 20 times more important than vertebrate predators. Important to whom?-A particular population? The daphnids? The community? Important in what way?-For calculating nutrient and energy budgets? For determining community structure and trophic networks? For quantifying stability?

In aquatic ecology there is an obsession with the silver bullet—the belief that a single factor can be found to explain ecosystem dynamics. For example, the limiting factor in eutrophication studies¹⁸,

the arguments on density-dependent versus independent population regulation, the controversy regarding whether competition or predation regulates the intertidal zone and now the pelagic zone. and the suggestions that aquatic ecosystems should be organized around the axis of body size. Some of these are parameter inputs. They do not control the ecosystem but rather set particular variables in motion. Variables included within a network possess similar rates whereas parameters are faster or slower. Wurtsbaugh et al. believe that fish are a variable—this may be true for littoral species in particular. In testing the Gull Lake data set with loop analysis, it seems that smelt act as a parameter input to Chaoborus spp. and large Daphnia pulex. Inclusion of smelt as a variable reduced the agreement of model predictions with the data. In fact, smelt are not even the predominant input-those enter at nutrient and algal levels. This is why I stated that "smelt probably have little effect on the myriad of

species". It is not possible to take one predation link out of a whole ecological network and declare that this controls the system or is the most important part of the dynamics¹⁸. The effect of any given parameter or variable on another variable is a consequence of the configuration of the whole network. In addition, indirect pathways often swamp direct ones. Smelt have reduced Chaoborus spp. populations, which in turn have eased the predation pressure on many small prey species. Thus, ignoring indirect pathways could cause substantial overestimates of smelt predation. Similar results have been noted elsewhere 19. This positive effect on small species demonstrates that ecologists should not hasten to load their ecological pistols with silver bullets for they will undoubtedly be caught in the cross-fire.

Now complete in 8 volumes . . . The Biochemistry of Plants

A Comprehensive Treatise

edited by P.K. Stumpf and E.E. Conn

From the reviews

"On the scores of currency and authority, these volumes rate very high. . . . Chapters are written by exactly the right people, and literature references extend into 1979. . . . As an overall recommendation, every plant biochemist should have Volume 1 of this treatise. it not only sets the cytological stage for all the rest, but it also contains brief summaries of most of the important topics that are discussed fully in other volumes. . . . After acquiring Volume, 1, each person will probably have a different second choice, but undoubtedly, there is at least one more volume that anyone in the field of plant biochemistry must have; and libraries must have them all."

Molecular Interactions Volume 2

edited by **H. Ratajczak,** Institute of Chemistry, University of Wroclaw, Poland,

and W.J. Orville-Thomas, Department of Chemistry and Applied Chemistry, University of Salford

This series of volumes will cover both theoretical progress made in the field of molecular interactions as well as the developments and applications of new experimental methods and techniques to study interactions between molecules.

This volume is devoted to some specific properties and the significance of strong molecular interactions of the hydrogen bond and electron donor-acceptor types in molecular biology and solid state physics, to the applications of selected physical methods to the study of electronic structure and properties of molecular complexes, and to electronic excited states of molecular systems. *Molecular Interactions Series*

April 1981 0471 27681 2

652 pages \$107.25/£39.00

Liquid Phase High Pressure Chemistry

by $\dot{\text{N.S.}}$ Isaacs, Department of Chemistry, The University of Reading

Concerned with the effects of pressure upon physical properties of matter and in particular on chemical reactivity. It emphasises the information which may be obtained concerning mechanisms of chemical and biochemical reactions by the use of applied pressure to determine volumes of activation or of reaction. Examples are taken from a very wide range of reaction types, both organic and inorganic, and the techniques for making such measurements are discussed.

February 1981 0471 27849 1

422 pages \$90.25/£33.00

Advances in Chemical Physics, Volume 46

edited by I. Prigogine, University of Brussels, and S.A. Rice, University of Chicago

This volume covers: Penetrable Sphere Models of Liquid-Vapor Equilibrium; Theory of Inhomogeneous Electron Systems; Spin-Density-Functional Formalism; Theories of Lipid Monolayers; The Reaction F + H2 - HF ± H; Nonradiative Processes in Small Molecules in Low Temperature Solids; Density Operator Description of Excitonic Absorption and Motion in Finite Molecular Systems; Heterogeneous Reaction Dynamics; Index.

April 1981 0471 08295 3 440 pages \$80.00/£38.10

Basics of Electroorganic Synthesis

by D.K. Kyriacou, The Dow Chemical Company, Pittsburgh

Illuminates fundamental electrochemical ideas and principles by means of selecting examples from the literature and the author's own researches, demonstrating the "practical unity" of organic chemistry in a concise clear manner. It describes the general electroorganic reaction and illustrates the general mode of concepts and applications in the area of electrosynthesis.

April 1981 0471 07975 8

192 pages \$36.75/£17.50

Flow Injection Analysis

by J. Růžička and E.H. Hansen, both of the Technical University of Denmark

Flow Injection Analysis, a new tool for automation of assay of discrete samples, is examined. The book gives detailed treatment of the parameters governing dispersion and describes how these parameters can be manipulated to optimize a given analytical procedure. FIA can apply to any chemical reaction whose product is detectable by standard analytical methods: spectroscopy, potentiometry, nephelometry or voltammetry. It also gives a complete account of construction and components of FIA apparatus, of FIA techniques and methods, and of FIA experimental approaches.

Chemical Analysis Series Vol. 62; Series Editors: **D.J. Elving** and **J.M. Winefordner**

Mechanisms of scientific revolution

G. N. Cantor

HISTORIANS of science have for a long time been interested in periods of major, rapid and partially discontinuous change in science. The most radical of these changes dates from, roughly, the first half of the seventeenth century and is generally known as the scientific revolution. Other more parochial revolutions, such as the Darwinian revolution, have also attracted much attention. In physics two main periods perhaps deserve the appellation 'revolution'; one associated with Fresnel's work on light, Carnot's and Fourier's on heat and other developments in the late eighteenth and early nineteenth centuries, and the other related to the rise of quantum and relativity theories a century later. Whether we decide to characterize either of these as a "revolution" depends on how we define the term in respect to changes in many facets of science.

Enrico Bellone's A World on Paper: Studies on the Second Scientific Revolution is concerned, as the sub-title suggests, with substantiating the claim that a revolution occurred in physics in the late eighteenth and early nineteenth centuries. The author claims that during this period physics became more mathematical, theoretical and abstracted from experience; physicists thus constructing "a world on paper". This book, first published in Italian in 1976, now appears in English translation. Stillman Drake, an authority on Galileo, has provided a somewhat eulogistic foreword. Bellone's book encompasses an important topic for current historical research, since despite the considerable amount of respectable secondary literature on this period there is comparatively little of a synthesizing nature. Unfortunately, this study is disappointing and fails to achieve its objective.

Problems arise partly because Bellone, a professor of the history of science at the University of Genoa, is anxious to demolish what he sees as two pernicious and pervasive doctrines. First, he intends to refute the view, which he appears to attribute indiscriminately to philosophers and most historians of science, that from the seventeenth to the end of the nineteenth century physics was dominated by the doctrine of mechanism. Not only does he fail to explain what he understands by this term but he also does not name his opponents, with the exception of Pierre Duhem. Yet Duhem's aim was to contrast the British tendency to construct mechanical models of physical phenomena

A World on Paper: Studies on the Second Scientific Revolution. By Enrico Bellone. Pp.220. ISBN 0-262-02147-1. (MIT Press: 1980.) \$20.25, £10.50.

with the continental methods of mathematical abstraction. The Aim and Structure of Physical Theory was published 75 years ago and no respectable historian or philosopher of science in recent years has championed any simplistic thesis concerning the total dominance of mechanism during the nineteenth century. We can conclude that Bellone has set up a straw man as his major opponent.

The second of Bellone's opponents is less of a straw man than an inappropriate one. Apparently with Kuhn, Popper, Feverabend and Lakatos in mind, he attacks those philosophers who have proposed general theories of scientific development. However, in order to controvert, for example, Kuhn's theory it is necessary to show that either it is intrinsically incoherent or it does not accord with the actual development of science. Bellone attempts a rather inadequate variant of the latter strategy by arguing in five casestudies that physicists have articulated their own views about scientific method and have not been indebted to philosophers of science, least of all to those who espoused mechanism.

By far the longest study is an attempt to show that, contrary to Duhem's characterization, Kelvin was not a mechanist. To substantiate this claim the author discusses Kelvin's work in such areas as energy conservation and the vortex atom hypothesis. However, he seems prepared to concede that Kelvin deployed mechanistic hypotheses and analogies provided they were adequately grounded on known physical laws and expressed in mathematical terms. More positively he interprets Kelvin as being centrally concerned with inductively discovered physical laws and prepared to employ mathematics only as a useful tool. These attitudes are traced to the views of John Herschel and Thomas Reid. Kelvin's empiricist philosophy is contrasted, in the second study, with that of Boltzmann who propounded a mathematical and highly abstract form of physical theorizing which set him against Mach's sensationalism and Ostwald's theory of energetics, and also led to his work on probability calculus. Of particular importance to Bellone is Boltzmann's partial rejection of mechanistic explanations.

The third study is largely concerned with Ampère who is interpreted as having rejected action-at-a-distance forces - as championed by Newton and Laplace and adopted a contact-action ether theory of electromagnetism. There follows an essay contrasting the fluid theory of electricity held by the Abbé Nollet in the 1740s with the mathematical instrumentalism propounded by Cavendish a quarter of a century later. Finally we return to the Kelvin-Boltzmann dispute over the respective roles of mathematics and experience and to Kelvin's recognition in 1900 that physics was facing two major problems: first the problem of reconciling ether theory with the Michelson-Morley experiment and, second, the inadequacy of the Maxwell-Boltzmann theorem for the equipartition of energy. These difficulties perceived at the end of the nineteenth century are interpreted by Bellone as indicating continuity with twentiethcentury physics; thus, in his opinion, no scientific revolution occurred early this century.

I hope that I have accurately conveyed the author's major claims since I found this a surprisingly difficult, even opaque, book. While admiring Bellone's courage in attempting to cover a major historical topic, I encountered several difficulties with his thesis. Some problems stem from disagreements with his historical claims. To give two examples: there is strong evidence, some of which is cited in this book, that Ampère did not subscribe to a contact-action ether, and Kelvin's philosophy cannot be simply traced back to Reid's - indeed they differed radically over the question of hypotheses and analogies. Other difficulties arise because although the book contains summaries of various writers' highly interesting views on mathematics, experimentation, theory and mechanics, the presentation of these issues lacks coherence and is weak in analysis, so that the reader is frequently assailed by: ambiguous statements and points which need both clarification and evidential support.

Yet more problems stem from the historiography which is based on what the author calls the "scientist's dictionary" (considered by Professor Drake to be Bellone's major contribution to the study of history). The dictionary of a scientist contains, it appears, the set of his currently adopted ideas. If I have interpreted Bellone correctly, then his theory of dictionaries is unhelpful if not positively misleading.

There are many significant dissimilarities between a mind and a dictionary: a dictionary, unlike a mind, contains only definitions of words, is open to public scrutiny and so on. How are we to construct a scientist's (private) dictionary from his public statements when the latter are often shaped for the audience for which they are intended? Given these and similar queries it is unfortunate that Bellone did not discuss this theory in much greater detail.

Bellone's notion of the scientist's dictionary has a further consequence for his historical claim that a revolution occurred in physics in the late eighteenth and early nineteenth centuries. Revolutions have, as Kuhn insisted, a social component which he expressed in terms of paradigm change being a change in consensus among the members of a scientific community. Even if one does not agree with the details of Kuhn's thesis it would appear difficult for the historian interested in large-scale changes in science to omit this social dimension. Yet this is precisely what Bellone does. According to

his theory, each scientist maintains his own dictionary and yet Bellone offers the historian no means of moving from individual dictionaries to an understanding of broader historical processes. Indeed, his failure to appreciate the latter leaves the reader unclear as to what constituted the "second scientific revolution".

Unfortunately, the author conveys the impression that he is divorced from the main currents of historical scholarship. An examination of the book's endnotes reveals surprisingly few references to the major secondary works on the subjects he discusses. His indiscriminate use of terms such as deduction, crucial experiment. common sense, scientific revolution, mechanism and Newtonianism indicates that he is not aware of the specific meaning conventionally attached to them. Finally, it is surely only ignorance of recent scholarship that could have led the author to construct his book as an attack on Duhem's outmoded thesis.

G. N. Cantor is a Lecturer in the Department of Philosophy at the University of Leeds.

Across the spectrum of IR astronomy

R.F. Carswell

Infrared Astronomy. International Astronomical Union Symposium No. 96. Edited by C.G. Wynn-Williams and D.P. Cruikshank. Pp.376. ISBN hbk 90-277-1277-1; ISBN pbk 90-277-1228-X. (Reidel: 1981.) Hbk Dfl.90, \$47.50; pbk Dfl.45, \$23.50.

FEW branches of astronomy have made such rapid progress in the past few years as the infrared. With the continuing development of modern detector systems, and in particular the availability of four telescopes high on Mauna Kea in Hawaii above most of the atmospheric absorption, there is every expectation that this will continue. It was therefore appropriate that a symposium on infrared astronomy should be held in Hawaii last year, drawing together contributions from many of the most active people in the field.

The papers included in the proceedings reflect the diversity of topics to which infrared astronomy is making its significant, and often unique, contribution. Articles on planetary studies, protostellar objects, molecular clouds, dust, nebular emission lines, stars in external galaxies, and active galactic nuclei show just how wide the range is. The often dull (to an outside astronomer) technical papers describing detector systems were deliberately excluded from the symposium, and the editors chose to include only reviews on each topic rather than all the inevitable specialist results normally heard at such symposia. The result is a volume which summarizes the present state of the subject well and gives an idea of the rapid advances being made without the nonspecialist reader having to wade through a mass of detail.

To choose a few at random, the three descriptions by Evans, Hyland and Thompson highlight the value of infrared studies of the highly obscured regions where star formation is occurring, and provide useful summaries for the relatively ignorant such as myself. The review of the reviews on this topic by Zuckerman helps to give the overall picture. In an area where I have more expertise, Soifer and Neugebauer give us a comprehensive survey of the properties of active galactic nuclei and quasars.

The final summary by Longair states succinctly what emerges from the proceedings in general. Infrared astronomy is proving to be useful in probing an increasingly diverse range of astrophysical questions and, with future developments, such as grating spectrometers, area detectors and infrared astronomy satellites, the trend towards "in depth" studies of particular classes of objects at all wavelengths is likely to continue. Thus, a book on infrared astronomy is likely to give way to more specialist collections. In the meantime, this volume provides a useful, up-to-date review of the entire field.

R.F. Carswell is at the Institute of Astronomy, Cambridge.

Hot history

P.T. Landsberg

The Tragicomical History of Thermodynamics 1822–1854. Studies in the History of Mathematics and Physical Sciences, 4. By C. Truesdell. Pp.372. ISBN 3-540-90403-4. (Springer-Verlag: 1981.) DM99, \$58.50.

WHAT is the meaning of the following result: "If the total heat of a homogeneous and uniformly hot substance be conceived to be divided into any number of equal parts, the effects of those parts in causing work to be performed are equal"? If this should not be quite clear, the following may help: "If the absolute temperature of any uniformly hot substance be divided into any number of equal parts, the effect of those parts in causing work to be performed are equal". These are quotes from William John Macquorn Rankine (1820-1872), a Scottish mining engineer, writer on thermodynamics, inventor of the word "adiabatic". They are his version of the second law of thermodynamics as given in his Manual of the Steam Engine which saw many editions, starting in 1859. Little wonder, then, that James Clerk Maxwell felt in 1878 that anyone who actually understood these remarks could explain thermodynamically what Tennyson had said of the great Duke:

whose eighty winters froze with one rebuke All great self-seekers trampling on the right.

If oscillations of this order in the clarity of conceptions concerning thermodynamics could take place *after* the period covered in Truesdell's book, it is perhaps not surprising that the period itself also furnishes many challenges to those who come in today to tidy up the errors of the founding fathers of the subject. This is precisely what Truesdell seeks to do (the above quotations will not be found in this book).

Where Maxwell proceeded with delicacy and humour, Truesdell is hard-hitting, hoping to raise in this way the subject from the "Dismal Swamp of Obscurity that from the first it was and that to-day in common instruction it is" (p.6). Leaving an assessment of this provocative remark to the many students and teachers of the subject, the book deals with Truesdell's rediscovery (following J. Moutier) of F. Reech (1805-1884) and has chapters or sections on Carnot, Helmholtz (The Conservation of Force being described as his weakest paper), Fourier, Clausius, Rankine, Kelvin and many others, mathematical aspects being given prominence.

The teaching of the subject can conveniently start with the introduction of specific and latent heat functions C and l defined in a usual notation by:

 $dQ = C_v dT + l_v dV = C_v dT + l_v dp.$

To these relations a third relation may be

added, which is not independent but yields a pleasant symmetry:

$$dQ = m_v dV + m_n dp.$$

This procedure has been used in a number of text books, including my own. Truesdell relates it to what he calls the "Doctrine of Latent and Specific Heats".

The book makes interesting reading and in its emphasis on the history of mathematical formulations of thermodynamics it breaks new ground. It suffers by the awkwardness of the chapter arrangements, cross references and notation, which makes it hard to read, and by the very limited references to the writings of contemporary historians of science, which sets it apart from current historical research. Not even Clausius' 1872 paper on the history of the mechanical theory of heat is cited as a source. I conclude with quotations illuminating the harsh ethos of

Of Laplace: As a physicist he preferred contorted structural hypothesis, as a mathematician he was unusually loose, even for his day [p.41].

Of Fourier: I doubt if any critical reader today would find in his book much insight into nature beyond that common in works of his predecessors and contemporaries [p.76].

"This unhappy quality is the tough and tortuous thread of the plot of the tragicomedy. It began with Laplace and was spun out by Fourier" (p.77).

P.T. Landsberg is Professor of Mathematics at the University of Southampton.

Will plant biochemistry go to the ball?

Philip Rubery

The Biochemistry of Plants: A Comprehensive Treatise. Editors-in-chief P.K. Stumpf and E.E. Conn. Vol.1 The Plant Cell (edited by N.E. Tolbert), pp.699, ISBN 0-12-675401-2. Vol.2 Metabolism and Respiration (edited by David D. Davies), pp.687, ISBN 0-12-675402-0. Vol.3 Carbohydrates: Structure and Function (edited by Jack Preiss), pp.638, ISBN 0-12-675403-9. (Academic: 1980.) \$65, £43 per volume.

A RECENT issue of Trends in Biochemical Sciences carried the headline "Plant biochemistry - a Cinderella too long". Does the publication of a comprehensive treatise on the biochemistry of plants herald the arrival of this poor relation in good society? As the editors comment in their general preface, the study of plants has had a mixed reception in the biochemical community. Thus the treatise aims not only to instruct but also to inspire - indeed, evangelize.

The first volume is largely self-contained and is organized into chapters centring on particular organelles and cellular membrane components which collectively cover many of the topics dealt with under the more system-based approach of Vols 2 and 3. Indeed, from reading all three volumes one theme that constantly recurs is the unity of plant cells and the interdepen-

Volumes 4 (Lipids: Structure and Function), 5 (Amino Acids and Derivatives) and 6 (Proteins and Nucleic Acids) in this series have now appeared. The last two volumes making up the Treatise (Vol.7 Secondary Plant Products and Vol.8 Photosynthesis) are scheduled for publication shortly. The completed series will be reviewed in Nature at a later date.

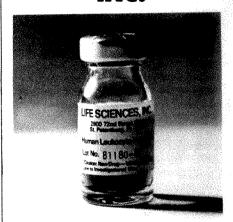

dence of organelles. For example, an overall account of the current status of carbon flow and compartmentalization in photorespiration and gluconeogenesis from fat can be synthesized from articles in Vol.1 on microbodies, on mitochondria and on chloroplasts; in Vol.2 on control of carbohydrate oxidation and on photorespiration; and in Vol.3 on integration of carbohydrate metabolism. The glyoxylate cycle is also covered in Vol.4 and a further chapter on photorespiration is promised for Vol.8.

One of the primary goals of a treatise such as this is to provide authoritative accounts of major areas which embody a large corpus of research. Many of the chapters fulfil this aim well - those on sugar nucleotide transformations (Vol.3), polysaccharide solution conformation (Vol.3), development and evolution of plastids (Vol. 1) and mitochondrial electron transport and energy coupling (Vol.2) are particularly good. The chapter on primary cell walls (Vol.1) includes a welcome critical review of the evidence for covalent linkages between macromolecules having a key role in wall structure.

A comprehensive account of plant biochemistry has other important tasks to perform. For instance, the applicability to plants of research strategies evolved in other contexts should be assessed and publicized. This is epitomized by ap Rees (Vol.3) in his consideration of the theoretical and experimental approaches to the regulation of hexose phosphate metabolism along the lines influentially described by Newsholme and Start in Regulation in Metabolism (Wiley, 1973). Turner and Turner cover similar ground in Vol.2, where Wiskich also deals rather more phenomenologically with the control of the Krebs cycle.

Areas where plant biochemists are

demonstrably ignorant compared to their animal colleagues (the Cinderella effect?) are frequently pointed out and many chapters suggest where plant horizons could be broadened or at least examined more closely. According to Storey (Vol.2), none of the mitochondrial redox flavoproteins has been characterized as an isolated enzyme. The contrast with the wealth of spectroscopic data available for plant mitochondria exemplifies the comparatively patchy sophistication of plant biochemistry. Similarly, the important enzyme thymidylate synthase, discussed by Cossins in Vol.2, has not been characterized from plant tissue. On a wider scale. the biochemistry of many basic physiological problems remains obscure, especially when they lie in the interstices of traditional major domains. For example, we have little detailed understanding of the differences in metabolite traffic, involved in energy supply and carbon skeleton provision, between chloroplasts, cytoplasm, mitochondria and peroxisomes in leaf cells in the light and the dark. Graham's chapter (Vol.2) on the effects of light on "dark" respiration addresses some of these questions. The excellent article on translocation of sucrose and oligosaccharides, by Giaquinta in Vol.3, combines a physiological and biochemical approach to highlight key problems such as the mechanism of sucrose unloading from phloem whose further elucidation could have agronomic and economic implications. It is important that plant biochemistry should, like mammalian biochemistry, be increasingly concerned with applying the burgeoning range of new techniques to essentially cellular problems.

As to omissions, I would have liked some treatment of the cytoskeleton in plants and also perhaps a chapter explicitly devoted to transport across the membranes of organelles. The virtual exclusion of growth substances from the consideration of cell wall dynamics and of seed reserve mobilization is also regrettable, although admittedly phytohormones are not within the plan of the treatise. Nevertheless, most topics that one would hope to find adumbrated by the volume titles are covered although the "metabolic" content of Vol.2 is largely carbohydrate; lipids, amino acids, proteins and nucleic acids, and secondary products being dealt with in Vols 4,5,6 and 7 respectively. Much of the contents of these three volumes and of the treatise as a whole are likely to remain valuable sources of reference and perspective for the rest of the decade. They are not expensive in today's terms for what they provide and the semi-autonomous nature of the volumes should enable a variety of permutations to serve the interests of different groups and individuals. The treatise is timely and, like Cinderella, the subject is of some promise.

Philip Rubery is a Lecturer in Biochemistry at the University of Cambridge

Muscle: from hypertension to erection

Andrew P. Somlyo

Smooth Muscle: An Assessment of Current Knowledge. Edited by E. Bülbring et al. Pp.576. ISBN 0-7131-4348-7/0-292-77569-5. (Edward Arnold/Texas University Press: 1981.) £45, \$95.

SMOOTH muscle cells in blood vessels. bladder, uterus, gastrointestinal tract and airways support and regulate, directly or indirectly, nearly all bodily functions. Nevertheless, physiologists, until recently, have shied away from studying these cells because of their small size, relatively poor ultrastructural organization and great individuality. Our knowledge of the cell physiology of smooth muscle, with a few notable exceptions, is largely due to studies conducted within the past 15 years and, thus, a timely subject for the stated aim of this book - "an assessment of current knowledge". The book is a "family affair"; the editors and contributors are Professor Bülbring of Oxford and her former pupils who, individually and in collaboration, have contributed vigorously to this field. Nevertheless, the volume is not parochial; geographically, the authors range from Oxford to continental Europe, including Russia, and through the United States to Australia and Japan. Intellectually, the contents extend to cover work from laboratories outside "the family" and successfully reconcile previously opposing views, such as the normal occurrence of graded changes in membrane potential in tonic smooth muscles and the existence of smooth muscle regulation by mechanisms independent of the membrane potential (pharmacomechanical coupling).

The major emphasis is on electrophysiology and ion transport, areas of research in which Professor Bülbring and her pupils have been most active. Of what is known about these subjects, the contributions by Brading, Casteels, Jones, Kuriyama and Tomita leave little uncovered. Jones, perhaps having planned successfully his chapter as the basis of a graduate course on smooth muscle, presents a particularly broad view, covering not only relevant aspects of the ultrastructure, electrophysiology and the ionic permeability of normal smooth muscle, but also the membrane properties of vascular smooth muscle altered by high blood pressure. Voltage clamping of smooth muscle is assessed with admirable caution by Bolton, Tomita and Vassort. The application of this technique to tissues having such complex geometries as smooth muscle is a terrain where most researchers fear to tread, and, therefore, the identification of the ionic currents responsible for action potentials in smooth muscles has been ambiguous. The task of identifying such currents is not made easier by the large variations among different smooth muscles in which the contributions of, respectively, sodium and calcium to

the early current are quite variable. Burnstock's contribution on smooth muscle development and innervation and Gabella's extensive discussion of the ultrastructure of smooth muscle successfully relate structure to function. Gabella, incidentally, also reflects the consensus of experienced electron microscopists that, in both relaxed and contracted smooth muscle, myosin is organized in thick filaments.

Given the highly individual properties of smooth muscle cells in different organs and the variety of their functions, the subjects to be covered are limited only by space and the authors' interests. These range from the aforementioned studies of vascular smooth muscle altered by hypertension to the role of penile blood vessels in erection. It may come as a surprise to some that erection is due to the relaxation of smooth muscle of the penile arteries, the flaccid state being the result of vasoconstriction.

The flaws of the book are minor, although the mistaken identification of one of the editors, a Professor of some years standing, as an Assistant Professor is certainly an editorial "blooper". There is considerable overlap between the various chapters covering electrophysiology and ion distribution, perhaps unavoidable in a multi-author volume that is the product of a single scientific "school", and also forgiveable in a book that boasts several thousand references dealing with this subject. It is not a textbook, since some important aspects of smooth muscle, including biochemistry, muscle mechanics and energetics did not fall within this group's research interests and are, therefore, discussed little or not at all. In this sense, this book and the recently published volume in the Handbook of Physiology series (Vascular Smooth Muscle; American Physiological Society, 1981), of which, I should confess, I am an editor, complement each other well; together they provide an encyclopaedic survey of the field.

Smooth Muscle: An Assessment of Current Knowledge brings us up to date with the use of electron probe analysis and ion selective electrodes, the latter in the laboratory of one of the editors, to verify the unusually high cytoplasmic concentration and activity of chloride in smooth muscle. Perhaps some of the more speculative aspects of this book, such as the postulated binding of calcium to the inner surface of smooth muscle plasma membrane, will eventually also be tested by direct methods.

The book is recommended to those with an interest in smooth muscle and to those wishing to learn about a cell system admirable in its infinite variety.

Andrew P. Somlyo is Professor of Physiology and Pathology and Director of the Pennsylvania Muscle Institute, University of Pennsylvania.

PRODUCT REVIEW

Alkalinity analyser

THE pump-colorimeter total alkalinity analyser is an addition to the Hach range of colorimetric instruments. Alkalinity is measured by colorimetric pH determination and three ranges are available: 0–50 mg 1^{-1} (as CaCO₃); 0–100 mg 1^{-1} ; and 0–500 mg 1^{-1} .

Circle No. 90 on Reader Enquiry Card.

Carbon rod atomizer

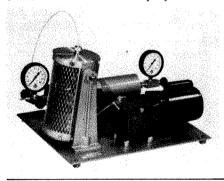

THE CRA-90 carbon rod atomizer, designed to overcome the sensitivity limitations of flame atomic absorption systems, is described in a brochure from Varian. The CRA-90 atomizes all the sample, as opposed to only 10% with flame atomization. Thus, a large signal is produced, which means that small sample sizes or very dilute solutions can be used. A typical analytical volume for the CRA-90 is 5 μ l, whereas flame methods usually require 5 ml.

Circle No. 91 on Reader Enquiry Card.

Shaker-type hydrogenator

Parr shaker-type hydrogenators, for testing chemicals with hydrogen in the presence of a catalyst, are described in a new catalogue. Parr shakers are used mainly for synthesizing or modifying organic compounds by catalytic hydrogenation, reduction or condensation. Pressures up to 5 atm and temperatures of up to 80°C can be achieved.

Circle No. 92 on Reader Enquiry Card.

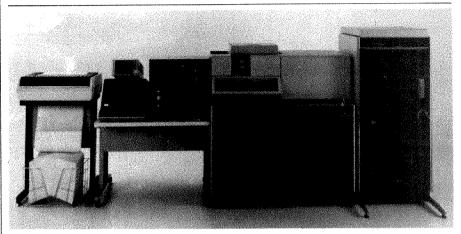

Bath circulators

New compact refrigerated bath circulators from Neslab Instruments occupy only 11×13 inches of bench space. With a temperature range of $-20^{\circ}\mathrm{C}$ to $+100^{\circ}\mathrm{C}$, the RTE-5 is designed principally as a circulator while the RTE-9 combines external circulation with a bath work area. Temperature stability of both models is $\pm 0.01^{\circ}\mathrm{C}$. Low level/high temperature safety is standard equipment. Two basic models, the RTE-5B and RTE-9B have been designed for applications which do not require the fine stability of the RTE-5 and RTE-9. These basic models have a temperature stability of $\pm 0.1^{\circ}\mathrm{C}$.

- PRODUCT REVIEW — AMERICAN CHEMICAL SOCIETY

The American Chemical Society Chemical Exposition is being held at the New York Hilton Hotel, New York City, USA from 24 to 26 August. The notes on these pages include information provided by the exhibitors. For further details circle the appropriate number on the reader enquiry card bound inside the journal.

Effluent analysis

Finnigan MAT has designed the organics-in-water analyzer (OWA) GC/MS system for monitoring and analysis of industrial waste water. For protracted, routine analysis of organic pollutants, the OWA GC/MS is reliable and simple to operate. Automated software routines make quantitative GC/MS analyses of any organic compounds rapid and precise. Data

acquisition can occur simultaneously with data processing to increase sample throughput. The system includes a fully automated Perkin-Elmer Sigma series microprocessor-controlled gas chromatograph and an automated Tekmar liquid sample concentrator, designed to EPA specifications for the analysis of volatile organics in water.

Circle No. 94 on Reader Enquiry Card.

Electronic microbalance

THE Mettler M3 electronic microbalance offers a weighing range of 0-150 mg and is readable to 1 µg. It has a weighing capacity of 3,050 mg, a built-in calibration weight and offers automatic calibration. Stabilization time is <5s. The weighing pan, digital display and controls are arranged in the operator's field of vision for comfortable operation. In addition, weighing can be done without delay as arrestment is not necessary when dialling tare weights. With a touch of the pan brake button, pan oscillations are quickly eliminated. The M3 has double-walled housing, double-glass weighing chamber and heat shield to protect the balance against dust and temperature.

Circle No. 95 on Reader Enquiry Card.

Oxygen analyser

CHANGES of as low as 0.001% O_2 can be detected using the S-3A oxygen analyser which continuously measures oxygen in gases. This sensitivity is combined with high stability, allowing highly accurate measurements. The S-3A can be used for oxygen uptake studies and for breath-bybreath analysis and alveolar oxygen measurement. It is newly available from Applied Electrochemistry.

Circle No. 96 on Reader Enquiry Card.

Voltammetric cell

A NEW voltammetric/polarography cell from IBM Instruments, Inc. features a high-density polypropylene top with 'O' ring adapters for variable positioning of electrodes and accessories. These adapters also have the advantage of avoiding the problem of freezing ground-glass joints. This cell can be used for various electrochemical studies ranging in volume from 2 to 30 ml. Cell top and bottom are quickly threaded for an airtight seal. A thermostatic jacket that threads to the cell is also available for constant temperature studies. Circle No. 97 on Reader Enquiry Card.

Ultrafiltration membranes

Two new ultrafiltration membranes from Nuclepore Corporation filter selectively on the basis of molecular weight rather than particle size. Type C membranes are intended for use in concentrating or removing proteins from solution. They have molecular-weight cutoffs from 500 to 100,000, are usable in the pH range 2–10 and have an exceptionally low affinity for proteins. Type F membranes are intended for use in the pH range 1–14 and are available with molecular-weight cutoffs from 5,000 to 1 million. These membranes are autoclavable and can withstand temperatures of up to 130°C.

Circle No. 98 on Reader Enquiry Card.

Isotope ratio MS

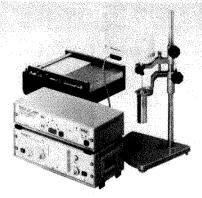

PRECISE automated measurement of isotope ratios for gases, uranium and metals is possible using a line of automated mass spectrometers from Finnigan MAT. Each system includes a desk-top calculator which controls the analysis run from sample inlet to printing of results. Applications are in geochemistry, mineralogy, nuclear fuel analysis, biology and soil science.

Post-column HPLC

THE URS 050 post-column reaction system has been designed by Kratos for derivatization procedures requiring the addition of a single reagent at room temperature (such as o-phthalaldehyde). The URS 050 performs all the necessary reaction steps: reagent addition, reagent/sample mixing, and reaction delay (to allow sufficient time for the derivatizing reaction to occur). Circle No. 107 on Reader Enquiry Card.

Thermocouple heads

Omega Engineering has developed new miniature aluminium heads for its line of thermocouple assemblies. Both corrosion and weather-resistant, they are designed to provide maximum protection for the electrical terminations of the thermocouple and connection to associated instruments.

Circle No. 108 on Reader Enquiry Card.

Electrophoresis chamber

THE new Semi-Micro II electrophoresis chamber from Gelman Sciences reduces buffer consumption to 200 ml per chamber. Three support bridges allow three membranes to be run simultaneously. The chamber works equally well with either Gelman's Sepraphore III or Super Sepraphore membrane, and is designed for use with Gelman's 8- or 4-place applicator. Circle No. 109 on Reader Enquiry Card.

Antisera

UNDILUTED antisera for RIA or nonisotopic immunoassay are now available from Miles Laboratories in two categories; undiluted antisera to hormones (for example, thyrotropic hormone) and undiluted antisera to drugs (digoxin, phenobarbital, gentamicin, tobramycin and amikacin).

Circle No. 110 on Reader Enquiry Card.

Scintillation cocktail

To meet the increasing demand for laboratory safety, Research Products International has developed Safety-Count, a new ready-to-use cocktail for liquid scintillation counting, designed for high efficiency counting of aqueous samples, salt-butter combinations and many other biological materials. Safety-Count uses a 100% aromatic hydrocarbon solvent. yielding a product with a flash point of 120°F TCC (tag closed cup). The cocktail is packaged in 4-l amber glass bottles covered with an impact-resistant plastic coating to reduce the risk of breakage. Circle No. 111 on Reader Enquiry Card.

HPLC column heater

MORE precise temperature control is a feature of the new column heater from SSI. Heaters may be mounted on to existing LC equipment but a horizontal mounting stand is available. Temperature can be controlled manually or by computer, from 10°C above ambient to 99°C with 0.1°C stability and 1°C repeatability; there is a 105°C positive safety cutoff. In addition to the standard 2-column block configuration for 15 cm and 25/30 cm 1/4-inch columns, SSI also offers standard heaters with blocks for 25/30 cm 1/4-inch and 3/4-inch columns or two 25/30 cm \(^3\kappa\) -inch columns. Circle No. 112 on Reader Enquiry Card.

Printing Counter/Timer

16 individual parallel inputs microprocessor based

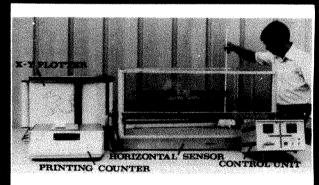

- * Prints results in programmable intervals (1 to 99 min.) or on demand.
- * Prints clock time: hours, min., sec.
- * Counts pulses or contact closures from 16 sources.
- * 99999 counts capacity in each channel.
- Totalizes time from 16 individual inputs with 4 msec, resolution.
- * Prints individual labels for each source.
- * Stores information on magnetic tape.
- * Functions as general purpose microcomputer.

RESEARCH Associate position in Cellular Immunology available immediately in the laboratory of Dr Donald E Mosier. Work involves the use of an existing panel of mono-clonal antibodies FACS analysis to characterize human B lymphocyte differentiation and function. Candidates should possess a PhD and/or MD and have prior experience in immunology. Familiarity with human lymphoid malignancies is highly desirable. Send curriculum vitae and three letters of reference to: Mary T Dixon, Personnel Dept, The Institute for Cancer Research, Fox Chase Cancer Center, 7701 Burholme Ave, Phila, PA 19111. Equal Opportunity/Affirmative Action Employer. (NW827)A

SENIOR Scientific Officer with good practical experience in HLA typing required to take technical charge of busy routine laboratory associated with a large Bone Marrow Donor Register. Work necessitates close collaboration with hospitals engaged in bone marrow transplantation and with departmental research projects. Ability to maintain high laboratory technical standards essential. Salary scale £5,500 to £7,110 plus London Weighting. Please write in first instance with CV to D C O James, Anthony Nolan Laboratories, St Mary Abbots Hospital, Marloes Road, London W8. (Tel: 01-937 (9392)A 2660).

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (University of London) Keppel Street (Gower Str) London WCIE 7HT DEPARTMENT OF MEDICAL PROTOZOOLOGY

RESEARCH FELLOW **GRADE RIb**

Applications are invited from good honours graduates in biological having experience in parasitology and/or pharmacology for a post to work with Professor W Peters for up to three years on the chemotherapy of Leishmaniasis.

Salary will be in the range £5,285 — £7,700 plus £967 London Weighting per annum.

Applications, consisting of full curriculum vitae and naming two referees, should be sent to Mr M R Morris, Senior Assistant Secretary at the School.

UNIVERSITY OF LONDON Institute of Neurology & Charing Cross Hospital MEDICAL SCHOOL POSTDOCTORAL RESEARCH ASSISTANT NEUROBIOLOGY/

required for a 3 year project, financed by the MRC, on neurotransmitters interactions in the nucleus accumbens. Biochemical and behavioural methods will be employed and experience in one or both areas would be an advantage.

NEUROPHARMACOLOGY

Appointment will be for one year in the first instance. Salary on the 1A range for Research and Analagous

Apply with CV and names of two referees to Dr J de Belleroche, Department of Biochemistry, Charing Cross Hospital Medical School, Fulham Palace Road, London W6. (9349)A

nature

seeks a

WASHINGTON CORRESPONDENT

to succeed David Dickson, who will be leaving his post in Washington on 31 March 1982. The post is central to Nature's reporting of developments affecting science in North America and elsewhere.

Applicants should be English-speaking, preferably with some first-hand knowledge of the United States and should also have

- a university degree (preferably in science)
- at least two years' experience of written journalism (preferably with a weekly or daily periodical, but not necessarily scientific)
- a broad interest in current affairs.

The successful applicant will be employed by Nature America Inc., initially for a fixed term (to be negotiated). To allow for a spell in the London office of Nature and a period of overlap in Washington, applicants should be able to be free no later than 1 March 1982.

Salary, travel allowances and other conditions of employment by negotiation.

Applications, including a full curriculum vitae, should be plainly marked "Job application" and addressed to the Editor, Nature, Macmillan Journals, 4 Little Essex St, London WC2R 3LF or Nature, 15 East 26 St, New York, NY 10010, to arrive (9324)A before 30 September 1981.

THE ROWETT RESEARCH INSTITUTE Bucksburn, Aberdeen AB2 9SB RESEARCH WORKER

Required to join a team investigating the use of anaerobic digesters in controlling pollution, and generating energy, from wastes originating in agriculture or agriculture-based industries.

Candidates should be interested in practical application as well as the more fundamental aspects of microbiological processes.

Applicants should possess a degree or HNC in a biological subject or in agricultural engineering with biological interests.

Appointment in the Scientific Officer grade (£4,809 to £6,480) or Higher Scientific Officer (£6,075 to £7,999 pa, scales subject to recent Civil Service award) starting salary according to qualifications and experience. At least five years post qualifying experience is required for HSO grading. Non-contributory superannuation scheme.

Applications, with full curriculum vitae, including the names of two referees should be sent to the Secretary of the Institute by 25 (9385)A September 1981.

UNIVERSITY OF CALIFORNIA Los Angeles Tenure Faculty Position ASSOCIATE OR FULL PROFESSOR IN THE FIELD OF PLANETARY **ATMOSPHERES**

A position has become available for a joint appointment in the Department of Atmospheric Sciences and the Institute of Geophysics and Planetary Physics.

Preference will be given to Senior Scientists with recognized accomplishments, whose interests are in global atmospheric composition and evolution of planetary atmospheres.

The position will require the successful candidate to develop a strong research program. moderate teaching load will be expected in the Department of Atmospheric Sciences.

Applicant deadline: 30 November 1981. Please send résumés to Hans Pruppacher, Chairman, Department of Atmospheric Sciences, University of California, Los Angeles California 90024. An Equa Opportunity/Affirmative Action Employer.

Research opportunities with ELI LILLY

Eli Lilly and Company is one of the world's largest producers of clinical pharmaceuticals, animal health and agrochemical products.

At our U.K. Research Centre, situated near Camberley in Surrey, we are actively engaged in basic research on a variety of projects and we currently have three vacancies within our research teams.

PHARMACOLOGIST

An experienced pharmacologist (Ph.D or B.Sc.) with an interest in the immune system is required to participate in an inter-active programme exploring the pharmacology of cytokines and effector substances.

BIOCHEMICAL PHARMACOLOGIST

A recent graduate biochemist/pharmacologist is required in our Central Nervous System Research Group. This multidisciplinary group is primarily interested in the

development of novel anti-psychotic drugs, and the successful candidate will be expected to continue existing projects and to initiate areas of novel research.

BIOLOGIST/IMMUNOLOGIST

A recent graduate (or H.N.C. equivalent) is required in our multi-disciplinary Immunology Research Group to work in areas of T-cell function, and antigen presentation and delayed-type hypersensitivity and to collaborate in hybridoma technology. Experience in tissue culture and/ or various immunological techniques would be an

For all these positions, a highly competitive salary is offered together with a non-contributory pension and life assurance scheme, subsidised B.U.P.A., 21 days' holiday, flexible working hours and relocation expenses where applicable.

Please write to: Miss S. M. Smith, Peronnel Manager.

LILLY RESEARCH CENTRE LIMITED

ERL WOOD MANOR, WINDLESHAM, SURREY. TEL: (0276) 73631

THE UNIVERSITY **OF SHEFFIELD DEPARTMENT OF PHYSICS**

Applications are invited from

men and women for an SERC POSTDOCTORAL RESEARCH ASSISTANT

to study the atomic structure of metallic alloy glasses, using neutron and X-ray diffraction techniques. The post involves joining an established group investigating both chemical and topological aspects of metallic glass structure. The neutron experiments will be made at AERE, Harwell and the ILL Grenoble. The work arises from collaboration between Dr N°Cowlam, Department of Physics, and Dr H A Davies, Department of Metallurgy and forms part of a wider programme of research on metallic glasses whose properties are currently of particular scientific and technological interest. Tenable for three years. Initial salary in the range £6,070 - £6,880 a year. Experience in neutron diffraction or in structural studies of amorphous materials an advantage.

Applications including curriculum vitae, and the names of two referees should be sent, as soon as possible to Dr N Cowlam/Dr H A Davies, c/o Department of Physics, The University, Sheffield S10 2TN, Quote Ref. R/627/G

(9345)A

A search is being conducted for an individual to fill an endowed **PROFESSORSHIP**

in the

DEPARTMENT OF TROPICAL PUBLIC HEALTH

We will consider candidates who are actively utilizing modern biological approaches to understand and combat tropical diseases, particularly those caused by parasites. Preference will be given to persons whose expertise includes the biology and biochemistry of membranes.

The person to be selected should be willing to interact with members of a multi-disciplinary department which includes molecular biologists, immunologists, cell and vector biologists, be able to establish working relationships with epidemiologists and field research workers, and be interested in teaching at the graduate and post graduate level.

Harvard University is an Equal Opportunity Employer committed to an Affirmative Action Program.

Send curriculum vitae, bibliography and three (3) references to: Dr Konrad Bloch, Chairman, Search Committee, Department of Nutrition, Harvard School of Public Health, 665 Huntington Avenue, Boston, Massachusetts, 02115.

(NW828)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (University of London) Keppel Street (Gower Str) London WCIE 7HT

Under a joint agreement between the Wellcome Foundation Limited and the London School of Hygiene and Tropical Medicine, a new laboratory is being formed to study the chemotherapy of protozoan diseases, particularly leishmaniasis and Chagas' Disease. The work of the laboratory will be under the direction of Dr R A Neal and located in the Department of Medical Protozoology (Professor W Peters).

A POSTDOCTORAL **FELLOW**

is now required to continue studies in progress on leishmaniasis chemothe-Applicants should have completed a PhD degree on aspects of parasitic protozao, eg biochemistry, that would be of relevance to the chemotherapy of these organisms. Experience in culture techniques would be an advantage. The appointment would be for up to three years.

The salary will be in the range £6,070 — £10,575 plus £967 London Weighting per annum.

Applications, consisting of full curriculum vitae and naming two referees, should be sent to the Senior Assistant Secretary at the School.

(9354)A

HEINEMANN EDUCATIONAL BOOKS

require an experienced

DESK EDITOR

to work in their Science and Mathematics department on all aspects of the publication process from receipt of manuscripts in-house through to publication including liaison with authors, marking up, commissioning artwork, proofreading, liaison with the departmental Production and Design Manager and generation of pub-licity material. The editor will work closely with a small team involved in the expansion of HEB's successful science and mathematics lists at primary, secondary and tertiary levels. There is considerable opportunity to become involved in the development of new projects.

The job would suit a graduate in science or mathematics with at least three years' relevant experience in publishing.

Salary will be at least £6,200, or more, commensurate with experience.

Applicants should write to Graham Taylor with full details of career to date

Heinemann Educational Books. 22 Becford Square, London WC1B 3HH

Biophysicist/ Bioengineer

Are you the seasoned professional to pilot our new venture?

If so, you'll have full responsibility for the development and sales positioning of a new business activity and you'll be applying your knowledge of cell culture and fermentation to the design, manufacture and marketing of diagnostic instrumentation and allied materials/equipment.

You'll need several years of solid experience in an industrial/educational environment . . . with emphasis on the formulation and packaging of biological/medical commercial applications . . . as well as an advanced degree in biophysics or bioengineering or its equivalent.

The new technology is fully developed . . . all ready for your implementation. Our compensation and benefits are liberal . . . and your future will grow along with the project's success.

Please send resume and salary history to:

BOX No NW304 Nature, 15E 26 St, New York NY 10010

(NW824)A

An Equal Opportunity Employer

NORTHGATE EXPLORATION

Northgate Exploration Limited, through its subsidiary Irish Base Metals Limited, is involved in extensive exploration programmes in Ireland. In order to supplement its existing team Irish Base Metals Limited has vacancies for the following positions.

JUNIOR EXPLORATION GEOLOGIST

Applications are invited from recent graduates in geology or an equivalent qualification.

EXPLORATION GEOLOGIST I

Applications are invited from geologists with 3-5 years experience in exploration for base metals and a strong background in geochemistry, geophysics and drill supervision.

EXPLORATION GEOLOGIST II

Applications are invited from geologists with 3-5 years experience in exploration for base metals in carbonate environments. For this position a strong background in carbonate petrology and statistics would be an asset.

SENIOR EXPLORATION GEOLOGIST

Applications are invited from geologist with 7-10 years experience in mineral exploration involving a variety of geological environments, particularly carbonates. For this position proven ability of crew supervision and conceptual thinking is essential.

Salaries and conditions of employment will be discussed at interview. Applications quoting references and including comprehensive curriculum vitae should be forwarded to: Mr Sean Egan, Administration Manager, Irish Base Metals Limited, 162 Clontarf Road, Dublin 3, Ireland. (9362)A

UNIVERSITY OF LONDON

DEPARTMENT OF BIOCHEMISTRY St. Thomas's Hospital Medical School, London, SE1 7EH

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from Postdoctoral Biochemists to work on a project supported by the British Diabetic Association to investigate the mechanisms of sugar transport into brain synaptosome preparations. The appointment is available from 1 October 1981.

Applications, accompanied by a curriculum vitae and the names of two referees, should be sent to Professor H S Bachelard, Department of Biochemistry, St Thomas's Hospital Medical School, London SE17EH. (9365)A

READVERTISEMENT MEMORIAL UNIVERSITY OF NEWFOUNDLAND St. John's Newfoundland

St John's, Newfoundland, Canada

DEPARTMENT OF

COMPUTER SCIENCE

HEAD

Applications are invited for the position of Head, Department of Computer Science in the Faculty of Science, Memorial University of Newfoundland. Position to be filled as soon as possible.

Candidates should have demonstrated teaching and scholarly research abilities indicative of senior rank, with a fairly broad background in computer science and the capabilities of exercising academic and administrative leadership. A PhD in Computer Science or related area is required.

The Head would be responsible for developing future research programs, including the introduction of a PhD program. An MSc program is already in existence. The undergaduate program is well established and is rapidly expanding with approximately three hundred full-time majors. At present there are nine full-time faculty members with additional post to be created. In addition there are several part-time Sessional Lecturers.

Departmental Computing facilities include a VAX 11/780 currently running under UNIX Version 7 Operating System and a PDP 11/34 and 11/10 also under UNIX. A large number of terminals, graphics equipment and other facilities are also available.

Canadians or Landed Immigrants will be given first preference. Salary is negotiable.

Please send curriculum vitae and the names of three references to: Dr PJ Heald, Dean of Science, Chemistry-Physics Building, C-335, Memorial University of Newfoundland, St John's, Newfoundland A1B 3X7, Canada. (NW823)A

FRESHWATER BIOLOGICAL ASSOCIATION BIOMETRICIAN/ STATISTICIAN

required for Windermere Laboratory to initiate research in biometry as applied to pupulation dynamics of benthos, plankton and fish, sampling freshwater organisms and chemical/physical variables and experimental studies in collaboration with biologists and chemists. Minimum of 2.1 honours degree in statistics/biometry/mathematics or science degree plus statistical training or experience. Conditions analogous to HSO/SSO in Civil Service, starting salary between £6,075 and £7,644 pa.

Full details: Secretary, FBA, The Ferry House, Ambleside, Cumbria LA22 0LP (096 62 2468). Closes 7 Sept. (9314)A

AUSTRALIA New South Wales

Department of Agriculture

Senior Livestock Research Officer

Agricultural Research Station, Trangie, N.S.W. POSITION NO AG. 81/247

Salary: A\$21,779 range A\$24.690.

Qualifications: Essential — Post-graduate degree in Animal Breeding and Genetics.

Duties: Responsible for directing and supervising the N.S.W. Department of Agriculture's Merino breeding activities. Successful applicant will have a major research programme on the inheritance of production characters in Merino sheep especially on the inheritance of wool production.

In addition will be responsible for development of breeding programmes in collaboration with Sheep and Wool Advisory Officers. Sheep breeding is part of a multi disciplinary animal production research group located at Trangie. This group has good laboratory and statistical support.

Accommodation: Single Officer accommodation or house for married applicant is available at the Research Station.

Inquiries: (Sydney (02) 217-5262 (Dr. G.E. Robards) Inspection of work location prior to interview is welcome. Applications on form 59 available from any N.S.W. Government Office are invited from persons irrespective of sex, race, marital status or physical impairment. Envelopes containing applications should be clearly marked "Confidential-Position No. Ag. 81/247 and forwarded to Personnel Resources Branch, Level 10 McKell Building, Rawson Place, Sydney. 2000, N.S.W., Australia by 11th September, 1981.

For the innovative, there's no place quite like Syva.

Discover creative freedom with the innovators in medical diagnostics.

We believe that talent, creativity and determination aren't worth much without a good place to use them. So over the years. Syva has been committed to providing our people with an environment conducive to creative freedom and independent thinking. And that philosophy has been an overwhelming success in turning medical diagnostic concepts into practical, life-giving contributions.

Syva's proprietary products are used for the measurement of therapeutic drugs, endogenous substances and abused drugs in the body, with continued research and development efforts promising many more applications. And the formation of our new Instrument Division will ensure that Syva flourishes as a full-service organization, providing instruments, as well as reagents, service, and education to our customers.

Just as our accomplishments in the past are the result of innovative contributions from highly skilled professionals, Syva's continued growth and success depend on more of the same-more innovations from talented microbiologists, biochemists, organic chemists, technical service representatives and sales representatives. And since we're depending on whole-hearted determination to continue our success, our people depend on us for one of the most attractive work environments in the industry.

From a style of participatory management that encourages free and open discussion to the most advanced facilities in the business; from the beautiful San Francisco Bay Area's wealth of cultural and recreational resources to competitive salaries and benefits, when you explore a career with Syva you'll find a place where your

Scientists/ Engineers

Genentech, Inc., a leader in the field of recombinant DNA research and manufacturing, is currently accepting applications for Research Associates, Scientists, and Engineers in the following disciplines:

- Protein Biochemistry
- Process Development
- Industrial Microbiology
- . Biochemical Engineering
- Chemical Engineering

Located on the beautiful San Francisco peninsula, we offer our employees excellent compensation and benefits, complemented by a stimulating, multi-disciplinary environment. To arrange interview appointment at the ACS Meeting August 23 - 27, please see our Representative at the Employment Clearing House at the Sheraton Center. Those unable to attend should send their curriculum vitae/resume with the names of three references to Professional Employment/#12-109.

Genentech, Inc.

THE WEIZMANN INSTITUTE OF SCIENCE ISRAEL

POST-DOCTORAL POSITION AVAILABLE

For electrophysiological studies in procaryotic cells, to learn the mechanisms of sensory transduction.

Applicants should have a PhD degree. Preference will given to those having research experience in electrophysiology or in measuring membrane potential using optical techniques.

Applications or requests for more details should be addressed to: The Weizmann Institute of Science, Membrane Research Department, 76100 Rehovot — Israel. (W405)A

UNIVERSITY OF GUELPH

DEAN OF THE COLLEGE OF BIOLOGICAL SCIENCE

Nominations and applications are sought for the position of Dean of Biological Science which will become vacant on 1 July, 1982. The College of Biological Science consists of the Department of Botany and Genetics, Microbiology, Nutrition, and Zoology, and the School of Human Biology and has approximately 90 faculty members. Approximately 2,000 students are enrolled in the undergraduate programmes in the College with 150 graduate students in Masters and PhD programmes. Research projects in the College cover a wide spectrum and attract considerable external funding. Strong academic leadership qualities and distinguished scholarly reputation, together with previous teaching and administrative experience are requirements for the position.

Applications and nominations should be sent by October 31, 1981 to: Dr. H. C. Clark, Vice-President, Academic, University of Guelph, Guelph, Ontario, Canada N1G 2W1. (NW825)A

BIOTECHNOLOGISTS

Graduates (2) and Technicians (2) are required by Cambridge Life Sciences Ltd, a new British biotechnology company based at the Cambridge Science Park, England.

The successful candidates will have had considerable experience of commercial scale biochemical production, particularly enzymes, and be familiar with the problems of scale-up from bench to pilot plant.

This is an excellent opportunity for scientists with initiative to work in this new and rapidly developing technology in a stimulating and pleasant environment.

Salaries are negotiable according to qualifications and experience.

Please write, enclosing full CV to:

Dr M. Gronow CAMBRIDGE LIFE SCIENCES LTD Science Park Milton Road Cambridge CB4 4BH

or phone 0223 835221

(9393)A

BIOPHYSICIST/ MOLECULAR GENETICIST

The Donner Laboratory, Lawrence Berkeley Laboratory, is seeking a Biophysicist/Molecular Geneticist to lead a research program designed to investigate the fundamental nature of mutational events in mammalian cells. Applicants should have a doctorate and an established record of creative research in the molecular mechanisms of mutation and altered gene expression.

Research experience in the effects of ionizing and ultraviolet radiation, and chemical mutagens and carcinogens on mammalian genomes is also desirable. Salary will depend on the level of achievement and professional maturity. Applications must be received by September 30, 1981.

Send curriculum vitae, publications list, and names and addresses of at least two references to: Dr Eleanor A. Blakely, Chairman, Biophysicist Search Committee; c/o Mr Ron Lowder, Lawrence Berkeley Laboratory, Personnel Office, One Cyclotron Road, Berkeley, CA 04720. An Affirmative action, equal opportunity employer, M/F/H.

READVERTISEMENT MEMORIAL UNIVERSITY OF NEWFOUNDLAND

St John's, Newfoundland, Canada

COMPUTER SCIENCE ASSISTANT/ASSOCIATE PROFESSORSHIPS

Applications are invited for fulltime, ternure-track appointments at the rank of Assistant or Associate Professor level, to commence at the earliest possible date. Applicants should have a PhD or nearing completion of a PhD in Computer-Science. Specialization in the areas of computer graphics, microprocessors, computer systems, data base systems or programming languages would be highly desirable.

Responsibilities will include teaching at the undergraduate and graduate levels, research and some committee work.

Departmental computing facilities include VAX 11/780 currently running under UNIX Version 7 Operating System and a PDP 11/34 and 11/10 also under UNIX. A large number of terminals, graphics equipment and other facilities are also available.

Canadians or Landed Immigrants will be given first preference. Salary is negotiable.

Please send curriculum vitae and names of three references to: Prof J M Foltz, Acting Chairperson, Department of Computer Science, Memorial University of Newfoundland, St John's, Newfoundland A1C 5S7, Canada. (NW822)A

Recombinant DNA Technology

Armos Corporation

due to expansion of its laboratories, is seeking additional PhD's familiar with:

- * Nucleic Acids Synthesis
- * Expression of Polypeptides in Bacteria or Yeast
- * Virology
- * Immunology
- * Protein Chemistry.

Qualified candidates will play an important role in the growth of the firm while doing research in this exciting field.

ARMOS offers an outstanding salary and benefits package, plus an attractive equity participation program. Female and minority applicants are encouraged to apply.

Please send curriculum vitae, reprints of pertinent publications, and letters of recommendation to ARMOS CORPORATION, 180 Kimball Way, South San Francisco, California 94080. (NW821)A

UNIVERSITY OF MELBOURNE FACULTY OF ENGINEERING APPROPRIATE TECHNOLOGY COORDINATOR

Applications are invited for the above-mentioned post at the level of Lecturer/Senior Lecturer (Limited Tenure). The appointment will be for three years commencing 1st December, 1981 or as soon as possible thereafter.

The Appropriate Technology Section was established to encourage and coordinate activity in the Faculty of Engineering in the technologies appropriate to the needs of developing countries, both in education and training and through research and development work. The Section is responsible for the Master's Programme in Development Technologies.

Applicants should have a degree in engineering or applied science, and have had professional experience in developing countries and a strong interest in their problems. Teaching experience is expected, and experience in some field of appropriate technology is desirable.

Salary in the ranges \$A19,821 — \$A26,037 and \$A26,593 — \$A30,995 per annum.

Further details of the position are available from the Dean of the Faculty of Engineering.

Further information regarding details of application procedure and conditions of appointment, is available from the Staff Officer, University of Melbourne, Parkville, 3052, Victoria, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on 36 September 1981. (9357)A

KING'S COLLEGE LONDON DEPARTMENT OF BIOPHYSICS POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral research assistantship to study the regulation of globin gene expression during the development of the frog, *Xenopus laevis*. Expertise in Molecular biology and a knowledge of vertebrate development would be beneficial. Post tenable for up to 3 years from 1 October 1981. Salary in the range £6,475 — £7,700 pa plus £967 London allowance. USS.

Apply in writing as soon as possible with a *curriculum vitae* and the names and addresses of two referees, to Dr R K Patient, Imperial Cancer Research Fund, Mill Hill, London NW7 1AD.

RESEARCH TECHNICIAN (Grade 3)

Applications are invited from suitably qualified persons interested in working on DNA gyrase and the enzymology of DNA supercoiling in bacteria and eukaryotes. Experience in the techniques of DNA biochemistry, protein chemistry or enzymology an advantage. This post, funded by the Cancer Research Campaign, commences on or around 12 October and is renewable annually for up to three years. Salary in the range £4,672 — £5,473 plus £1,027 London Allowance. 37 ½ hour week, Monday to Friday. Five weeks' annual holiday. Superannuation scheme.

Apply in writing by September 7 1981, with a curriculum vitae and the names and addresses of two referees, to Dr L M Fisher, Department of Biphysics, Kings College, 26-29, Drury Lane, London WC2B 5RL. (9377)A

YOU'VE GOT A BRIGHT IDEA

FOR NEW BIOLOGICAL OR CHEMICAL COMPOUNDS

WE HAVE THE CAPITAL TO DEVELOP NEW DRUGS

We are not a pharmaceutical firm but a Swiss-based, independent financial group which is prepared to let you participate in a capital venture for the exploitation of your project.

Our object: the development of new biological or chemical products with previous pharmalogical screening up to the stage of clinical tolerance and efficacy required to permit licensing negociations.

To obtain all the information required for initial selection, please write in English, French or German to:

DEBIOPHARM S.A. Petit-Chêne 38 - 1001 LAUSANNE (Switzerland). (W368)A

UNIVERSITY OF MELBOURNE READER/SENIOR LECTURER

(Two Positions) in the DEPARTMENT OF PHYSICS (RAAF ACADEMY)

Applications are invited for the above-mentioned positions. The Physics Department is located both within the grounds of the University and at Point Cook where the bulk of cadet teaching to BSc level is undertaken. The main areas of research are infrared, gamma-ray and neutron astrophysics, and remote sensing investigations of the lower atmosphere. Applicants should have expertise in one or other of these areas.

The appointment will be made to the Staff of the University of Melbourne and will be tenable upon University conditions initially for five years in the case of an appointment as Réader and for four years in the case of an appointment as Senior Lecturer. Either during the initial period or if confirmed by Council after the initial period, the appointment will continue until 31 December of the year immediately preceding that in which the proposed Defence Force Academy commences to operate, when the appointment with the University of Melbourne will terminate. The holder of the appointment will then have the right to transfer to the employment of the Defence Force Academy. The Department of Defence has entered into an agreement with the University of New South Wales whereby the University will establish a College of the University within the Defence Force Academy.

The Department of Defence will provide twelve months' formal notice prior to requiring a decision from a person in relation to the exercise of that right to transfer.

The Department of Defence will also arrange for removal to Canberra, in accordance with normal Commonwealth standards and procedures, for a person who transfers to the Defence Force Academy.

When the Defence Force Academy commences to operate, a person employed by the University in connection with the RAAF Academy who transfers to the Defence Force Academy will be employed by the Defence Force Academy under conditions not less favourable than those which that person enjoyed at the University.

Salary within the range: Reader \$A35,049 per annum; Senior Lecturer \$A26,593 to \$A30,995 per annum.

Salary and classification will be determined according to qualifications and experience.

The successful applicants will be expected to commence duties on 1st January, 1982.

Enquiries may be directed to Professor J A Thomas in the University.

Further information including details of application procedure and conditions of appointment are available from the Staff Officer, University of Melbourne, Parkville, 3052, Victoria, Australia, or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Applications close on 30 September 1981.

(9358)A

The Australian Institute of Marine Science RESEARCH POSITION

Chemical Oceanography

The Australian Institute of Marine Science was established as a Statutory Authority of the Commonwealth Government in 1972 and in 1977 moved into a modern comprehensively equipped laboratory complex at Cape Ferguson near Townsville. The Institute is well situated for studies in tropical marine science including phenomena and the land-sea interface, on the complex environment of the Great Barrier Reef and in the adjacent ocean. The ongoing programs of the Institute are augmented by active collaboration and interaction with visiting investigators from research organizations within Australia and overseas.

APPLICATIONS are invited from researchers with interests and experience in chemical and related aspects of Oceanography to take part in comprehensive investigations of the environment and living communities of the Great Barrier Reef. Within the overall program, an understanding is sought of the physical, chemical and biological interactions taking place within reefal systems and between those systems and adjacent waters.

QUALIFICATIONS: The appointee must possess PhD level qualification and preferably experience demonstrably applicable to the research program outlined.

SALARY: The salary offered shall be commensurate with the qualifications and experience of the successful candidate.

Applications including a complete C.V. and the names of at least three (3) but not more than five (5) referees should be forwarded to: The Secretary, Australian Institute of Marine Science, P.M.B. No. 3, M.S.O. Townsville, Q. 4810, Australia.

Closing date for applications is 30 September 1981.

(9351)A

UNIVERSITY OF STRATHCLYDE Applications are invited for a POSTDOCTORAL RESEARCH FELLOW and for TWO RESEARCH ASSISTANTS IN CARDIOVASCULAR

CARDIOVASCULAR
PHARMACOLOGY
in the
DEPARTMENT OF
PHYSIOLOGY AND
PHARMACOLOGY
details as follows

 Postdoctoral Research Fellow, financed by the British Heart Foundation for work on early post-infarction arrhythmias. Period two years. Salary Range IA £6,880 per annum.

2. Research Assistant, financed by the Scottish Home and Health Department to work on the cardiovascular effects of prolonged exposure to lead. Period two years. Salary Range IB £5,285 per annum. Registration for a higher degree possible.

3. Research Assisant, financed by the Medical Research Council to work on the release of vasoactive agents in shock. Period two and a half years. Salary Range IA up to £6,880 per annum. Registration for a higher degree possible.

USS benefit in each case.

Applications (quoting R15/81) including a brief curriculum vitae and the names of two referees should be sent to Professor J R Parratt, Royal College, University of Strathclyde, Glasgow G1 1XW as soon as possible, stating clearly the particular post in which interested. (9356)A

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF VETERINARY CLINICAL STUDIES

RESEARCH ASSISTANT PHYSIOLOGY/ BIOMECHANICS

Applications are invited from recent graduates with an interest in physiology and biomechanics to participate in an investigation into the mechanism of dilation of the sheep cervix at birth. The project is financed by the Wellcome Trust.

Initial salary will be either £5,285 or £5,675 per annum.

Applications, together with the names of three referees, should be received not later than 4th September, 1981, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/866/N. (9363)A

UNIVERSITY OF OXFORD University Laboratory of Physiology RESEARCH ASSISTANT GRADE IB

Salary £5,285 — £7,290

Applications are invited for the post of Research Assistant, supported by a grant form the National Institute of Health, Washington, USA, for research on the mechanism of action of antidiuretic hormone. Candidates should have an honours degree in Physiology, Biology or Biochemistry; experience in transport physiology or cell biology would be an advantage. The post is tenable until April 30th, 1984.

Applications stating age, qualifications and experience, and giving the names and addresses of two academic referees should be sent to: The Administrator, University Laboratory of Physiology, Oxford OXI 3PT. (9390)A

POSTDOCTORAL Fellows Research Associates and Technicians, Molecular Genetics and Neurobiology, University of Colorado. Applications are invited from individuals with PhD or MD to pursue studies on the molecular genetics of the mammalian brain. Emphasis is placed on use of recombinant DNA technology to study the structure and regulation of genes expressed postnatally. Background in nucleic acid chemistry is essential Technicians with experience in cell fraction and DNA-RNA hybridization are also needed. All positions have potential of leading to long term appointments. Beginning salary range \$18,000 - \$32,000. Travel expenses for relocation and meetings. Send CV, names and phone numbers of 3-5 references, and copies of recent publications to: William E Hahn, Professor, University of Colorado, School of Medicine, B-111, Denver, Colo. 80262. (NW818)A

KING'S COLLEGE LONDON (University of London) DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANT

to join a research group investigating the selective intracellular catabolism of abnormal proteins.

The position, funded by SRC, will be tenable for two years and the project has as its objective the purification and characterisation of a size-discrimination protease from rabbit reticulocytes.

Applicants should have experience in enzyme purification and protein chemistry, an interest in the mechanism of protein turnover would also be of advantage. Salary in the range £6,070 to £6,880 plus £967 London Allowance.

Applications, including curriculum vitae and names and addresses of two academic referees to Dr A R Hipkiss, Department of Biochemistry, King's College London, Strand, London WC2R 2LS as soon as possible.

(9359)A

UNIVERSITY OF DUNDEE DEPARTMENT OF BIOCHEMISTRY

Applications are invited from holders of good Honours degrees in Biochemistry or a related discipline for the post of

RESEARCH ASSISTANT

for a period of three years to work on a project to define the molecular mechanism in which plasma lipoproteins take part in lutropin-dependent progesterone synthesis by the corpus luteum. Salary according to age and experience in the range £5,285 — £6,070. Further particulars available from the Personnel Office, The University, Dundee DD1 4HN where applications should be returned by 17th Sep-

tember, 1981. Please quote Ref EST/50/81/J. (9344)A

UNIVERSITY OF MELBOURNE Australia CHAIR OF AGRICULTURE (ANIMAL SCIENCE)

Applications are invited for appointment to the Chair of Agriculture (Animal Science). Applicants should have had extensive research experience in some field of animal production and a demonstrated interest in and knowledge of agriculture.

Salary: \$A41,509 per annum.

Further information is available from the Registrar of the University or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF. All correspondence (marked 'Confidential') should be addressed to the Registrar, The University of Melbourne, Parkville, Victoria 3052, Australia

Applications close on 31 October 1981. (9372)A

UNIVERSITY OF MELBOURNE Australia CHAIR OF AGRICULTURE (PLANT SCIENCE)

Applications are invited for appointment to the Chair of Agriculture (Plant Science) in the School of Agriculture and Forestry.

Applicants should have had extensive research experience in some field of plant science related to plant production and a demonstrated interest in, and knowledge of agriculture.

Salary: \$A41,509 per annum.

Further information may be obtained from the Registrar of the University or from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. All correspondence (marked 'Confidential') should be addressed to the Registrar, The University of Melbourne, Parkville, Victoria 3052, Australia.

Applications close on 31 October 1981. (9373)A

RESEARCH FELLOW

Position will be available August 1, 1981. The work involves studies of molecular biology, including cloning of insulin receptor. Salary is \$15,000 (negotiable).

Please send résumé c/o

THE MATHILDA AND TERENCE KENNEDY INSTITUTE OF RHEUMATOLOGY

A position is available for a graduate

RESEARCH ASSISTANT

to work in the Biochemistry Division (Head: Dr Helen Muir). The research project will involve studies on the mechanism of biosynthesis and degradation of cartilage proteoglycans and collagen in relation to arthritis. The salary will be based on Range IB of the University of London scales for Research and Analogous staff.

Applications, including curriculum vitae and the names of two referees, should be sent to the General Secretary, The Mathilda and Terence Kennedy Institute of Rheumatology, Bute Gardens, Hammersmith W6 7DW. (9346)A

UNIVERSITY OF YORK

DEPARTMENT OF CHEMISTRY
Applications are invited from suitably
qualified persons for the post of

POST-DOCTORAL RESEARCH ASSISTANT

to work with Dr Guy Dodson on the ligation of haemoglobin crystallised from polyethylene glycol. The project is financed by the Medical Research Council and the appointment is available for three years from 1 October 1981.

The salary scale is £6,070 to £10,575 (Research 1A).

Closing date for applications — 11 September 1981.

Six copies of applications, including full curriculum vitae and naming three referees, should be sent to the Registrar, University of York, Heslington, York YO1 5DD, from whom further particulars are available. Please quote reference number 7097. (9347)A

ONTARIO CANCER TREATMENT & RESEARCH FOUNDATION LONDON CLINIC

London, Ontario, Canada

Applications are invited for the position of

CAREER SCIENTIST

from applicants with a minimum of 2-3 years post-doctoral research experience in the field of

CELL GENETICS

This position is to join a recently formed multidisciplinary research group studying the biology of cancer metastasis. The research objectives of the group are to gain an understanding of how the tumor microenvironment may modulate the metastatic potential of tumor cell populations.

The successful candidate will have proven expertise in a relevant field of research and the ability to develop an interactive research program with other members of the group. Salary will be commensurate with experience.

Applications to Dr K Moore, The Ontario Cancer Foundation, London Clinic, London, Ontario N6A 4G5. (NW829)A

UNIVERSITY COLLEGE GALWAY

DEPARTMENT OF PHYSICS
POST DOCTORAL
RESEARCH ASSISTANT

Applications are invited to work on laser transmission through laboratory generated fog and aerosol media. The work will also involve computer processing of data. Tenable for 2 years from 1 October 1981.

Applications with statement of research experience and the names of two referees should be sent as soon as possible to Dr S G Jennings, Department of Physics, University College Galway, Galway, Ireland. (Tel: Galway 7611 ext 704).

Salary within range IR£7,590 — IR£8,495 pa, depending on age and experience. (9361)A

FACULTY POSITIONS BIOCHEMISTRY

Tenure-track positions at a level to be determined by qualifications are open in the Biochemistry Department, School of Medicine at the University of North Carolina at Chapel Hill, We seek to establish expertise in any of the following research areas: cell surfaces, cell surface interactions and/or membrane biosynthesis; culture, genetics and/or differentiation of eukaryote cells; use of recombinant DNA methods in eukaryote molecular genetics; neurochemistry. Excellence in teaching and a desire to teach is expected.

Send curriculum vitae to: Dr Mary Ellen Jones, Chair, Biochemistry Department, University of North Carolina, Chapel Hill, NC 27514. We are keenly interested in attracting outstanding women and/or minority scientists to this department. Equal Opportunity/Affirmative Action Employer. (NW826)A

INGENE is a young and rapidly growing company creating industrial and biomedical products through genetic engineering technologies. Our laboratory facilities support projects utilizing recombinant DNA approaches, molecular genetics, cell culture, DNA synthesis and sequencing, and immunology. We are recruiting personnel in the fields of:

GENETIC
ENGINEERING/RECOMBINANT
DNA TECHNOLOGY
MOLECULAR
GENETICS/MICROBIOLOGY
BACTERIA/YEAST
IMMUNOLOGY/HYBRIDOMA
TECHNOLOGY
PROTEIN
BIOCHEMISTRY/ENZYMOLOGY
PLANT CELL GROWTH
AND
GENETICS/SEED SCIENCE

Opportunities exist for qualified PhD candidates with postdoctoral experience and an interest in participating in a stimulating, scholarly research program. We also are seeking technical personnel and postdoctoral fellows for work on diversified genetic engineering projects.

INGENE has attractive laboratory facilities in coastal Santa Monica, California, one of the most desirable commercial and residential sections in the Los Angeles area.

Please send a résumé and list of three references to: INGENE 1701 Colorado Avenue Santa Monica, CA 90404.

INGENE is an Equal Opportunity Employer and welcomes applications from qualified women and minorities.

(NW816)A

UNIVERSITY OF OXFORD NUFFIELD LABORATORY OF OPHTHALMOLOGY RESEARCH ASSISTANT

required for 3 years for a study of post-translational modification of proteins in cataract with special reference to diabetes and uraemia. Starting salary £5,285 (Scale 1B).

Further particulars may be obtained from Dr J J Harding, at the above address, to whom applications with full curriculum vitae and names of two referees should be sent as soon as possible. (9360)A

UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY TRANSLOCATION IN FUNGI

Applications are invited from those with experience in fungal or higher plant physiology for the post of Post-doctoral Senior Research Assistant (SERC supported) to work on long-distance translocation in Serpulla lacrimans with Professor D H Jennings. The post is tenable for up to three years from 1st October, 1981, at an initial salary within the range £6,070 — £6,880 per annum.

Applications, together with the names of 3 referees should be received not later than 7 September, 1981 by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote ref: RV/867/N. (9364)A

"POSITION Open" Postodoctoral — Utah in surface Raman spectroscopy. Experience in SERS and total internal reflection optics; interests in biophysical-bioengineering-biochemical applications of Raman spectroscopy desirable. SOUTH GLAMORGAN HEALTH AUTHORITY (T) UNIVERSITY HOSPITAL OF WALES

REGIONAL CYTOGENETICS SERVICE B/G CYTOGENETICISTS

Salary: £4,839 — £6,363 per annum

The above vacancy has arisen in this department which provides a comprehensive cytogenetics service. The person appointed will be required to work in all sections of the service.

Applicants should have a good honours degree in genetics or in one of the other Biological Sciences. Experience in tissue culture techniques and diagnostic cytogenetics will be an advantage, but not essential.

Further information can be obtained from: Peter J. Gregory, Department of Child Health, University Hospital of Wales, Heath Park, Cardiff. Tel: (0222) 755944 ext 2287.

Application forms available from: Personnel Department, University Hospital of Wales, Heath Park, Cardiff. Please enclose S.A.E.

Closing Date: 10th September 1981.

(9386)A

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)

DEPARTMENT OF HAEMATOLOGY

TECHNICIAN

required to work with a team carrying out clinical bone marrow transplantation. Duties include tissue typing, mixed lymphocyte culturing and carrying out various immunological assays. Experience in any of these fields or in haematological techniques desirable. This is a post for someone with initiative and interested in research projects. The post is funded by the Leukaemia Research Fund and is tenable for two years.

Salary up to £5,284 plus London Allowance (under review), initial placing dependent on age and qualifications.

Application forms and further particulars are available from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 7/233.

(9353)A

UNIVERSITY OF OXFORD NUFFIELD DEPARTMENT OF

ORTHOPAEDIC SURGERY

MRC BONE RESEARCH LABORATORY

Applications are invited for two posts to work on the isolation and characterization of factors that induce the differentiation of bone cells.

(1) POSTDOCTORAL RESEARCH ASSISTANTSHIP

Starting salary (Range 1A) — £6,070 — £7,290 pa for biochemists with experience in protein isolation + cell culture techniques

(2) MEDICAL LABORATORY SCIENTIFIC OFFICER

Salary range — £4,851 — £5,334 for technical assistance with above project

The posts are supported by MRC for a three year period. Applications with full curriculum vitae and names and addresses of three referees to Dr J T Triffitt MRC Bone Research Laboratory, Nuffield Orthopaedic Centre, Oxford OX3 7LD, as soon as possible. (9367)A

UNIVERSITY OF EDINBURGH DEPARTMENT OF ZOOLOGY POSTDOCTORAL BIOCHEMIST

Applications are invited for a postdoctoral research fellowship on a cancer research campaign supported project on cell surface glycoproteins in chronic lymphocyte leukemia supervised by Dr A H Maddy. Previous experience in membrane or protein biochemistry would be an advantage but candidates of other backgrounds would also be considered.

The post is for three years starting from October 1st 1981, or as soon as possible thereafter, with a research range 1A salary scale and superannuation.

Applications with curriculum vitae and the names and addresses of two referees should be sent to Dr A H Maddy, Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh EH9 3JT, from whom further details may be obtained. Please quote reference No. 5047. (9380)A

RESEARCH ASSISTANT

Immunologist/biochemist required to work as part of a team investigating immune reactions against liver cell membrane antigens in relation to autoimmune liver disease. An interest in characterisation of monoclonal antibody specificities and experience in enzyme-linked immunoassays and related techniques will be an advantage. The post is funded for 2 years in the first instance at a salary of up to £6,475 plus £967 London Weighting Allowance subject to the usual conditions.

Further information may be obtained from Dr I G McFarlane, Liver Unit, King's College Hospital (telephone: 01-274 6222 ext 2747).

Applications giving full curriculum vitae plus names and addresses of two referees should be sent to the Secretary, King's College Hospital Medical School, Denmark Hill, London SE5 8RX. Closing date 30th September 1981. (9355)A

UNIVERSITY OF FLORIDA DEPARTMENT OF MEDICINE University of Florida seeks

Scientist for appointment as
ASSISTANT PROFESSOR
OF MEDICINE

to join Medical Oncology Research team primarily involved in immunology and experimental Hematology. Candidates must have a doctoral degree (PhD or equivalent), at least 2 years experience, and demonstrated research productivity in human cellular immunology. Responsibility will include teaching at all levels. Salary \$23,000—negotiable.

Application recruiting deadline 12-31-81, anticipated starting date April 1, 1982. Contact Roy S Weiner, MD, Division of Oncology, Box J-277, J Hillis Miller Health Center, University of Florida, Gainesville, Florida 32610. An Equal Employment Opportunity/Affirmative Action Employer. (NW820)A

UNIVERSITY OF LEICESTER DEPARTMENTS OF PHYSIOLOGY

AND MEDICINE

GRADE 3 TECHNICIAN

A Grade 3 Technician is required to assist in laboratory studies into electrolyte transport by body cells in relation to blood pressure. The post is financed by the Medical Research Council and is tenable in the first instance for one year and is renewable for a further two years. The project will be carried out jointly in the two departments under the supervision of Professor J D Swales, Dr H Thurston and Professor R Whittam.

Previous laboratory experiencen in a biological sciences department is desirable. Salary scale £4,672 to £5,473.

Applications including a curriculum vitae and the names of two referees should be sent to Professor J D Swales, Department of Medicine, Clinical Sciences Building, Leicester Royal Infirmary, Infirmary Square, Leicester LE2 7LX by 28th August 1981. (9369)A

UNIVERSITY OF WARWICK RESEARCH ASSOCIATE IN VIROLOGY

Applications are invited from biochemists, microbiologists and other suitably qualified candidates to work in the Department of Biological Sciences on an ARC funded project concerned with the epidemiology of rotaviruses. Candidates should have either an upper second class honours degree plus at least one years postgraduate experience or an MSc. The appointment on the salary Range IB scale: £5,285 pa — £7,700 pa is for three years.

Applications (no forms) should include a curriculum vitae and the names of two referees to the Academic Registrar, University of Warwick, Coventry CV4 7AL and quote Ref. No: 2/2A/81/0. Closing date for receipt of applications 4th September, 1981. (9387)A

FELLOWSHIPS

UNIVERSITY OF GLASGOW DEPARTMENT OF BOTANY POST-DOCTORAL RESEARCH FELLOWSHIP

A post is available for a molecular biologist or virologist to work on the replication of a plant rhabdovirus. This will involve the cloning in *Escherichia coli* of various viral RNAs. Previous experience of recombinant DNA techniques would be an advantage. Familiarity with plant viruses is not a prerequisite.

The post will be available from 1st October, 1981 for three years. Starting salary will be within range 1A of the scales for Research and Analogous staff (£6,070 - £6,880).

Applications giving the names of three referees should be sent to Dr J J Milner, Department of Botany, The University, Glasgow G12 8QQ by 18th September, 1981.

In reply please quote Ref. No. 4847. (9384)E

continued on page xxviii

UNIVERSITY OF CAPE TOWN Chief Technical Officer

Applications are invited for the above post which falls vacant on 1st April 1982 in the Department of Inorganic Chemistry. The successful applicant will take charge of the general workshop in the School of Chemical Sciences. Experience in metalwork, woodwork, instrument-making and the maintenance of scientific equipment and appropriate technical qualifications will be a recommendation for the post.

Appointment, according to qualifications and experience, will be made on the salary scale R13,905 \times 495 - R14,400 \times 735 - R15,135 \times 735 - R15,870 per annum.

Applications, (quoting ref. number AC/8) including the names and addresses of two referees, should be addressed to the Head, Department of Inorganic Chemistry, University of Cape Town, Rondebosch, 7700, South Africa not later than 30 September 1981.

The University's policy is not to discriminate in the appointment of staff on the grounds of sex, race or religion. Further information on the implementation of this policy is obtainable from the Registrar. (W404)A

THE OPEN UNIVERSITY **EARTH SCIENCES**

NERC RESEARCH **ASSISTANTSHIPS**

Troodos Deep Bore

As part of an international deep drilling project involving scientists from Canada, Cyprus, Denmark, Iceland, UK, USA and W. Germany, a grant has been awarded to Professor I. G. Gass from The Open University and Professor F. J. Vine from The University of East Anglia to study the Troodos ophiolite (Cyprus) by drilling.

Funds have been made available to employ two Research Assistants to work on geophysical aspects with Professor Vine (UEA) and petrological/geochemical aspects with Professor Gass (OU); these posts are available from 1st January 1982 for three years. This advertisement is for both posts. Candidates for the Open University Petrology-Geochemistry post should hold a good first degree in geology with a specialization and interest in the petrology and geochemistry of basicultrabasic igneous rocks. Candidates for the geophysics post should have undergraduate experience in geophysics and will be expected to investigate the physical properties of bore hole specimens at varying temperature and pressures.

Both candidates will be involved in field studies and be present during some if not all of the drilling programme. There may be an opportunity to study for a higher degree. Salary will be within the Research and Analogous 1B scale: £5,285 - £7,700 p.a. but not exceeding £6,880 p.a. at the highest point.

Further particulars and application forms are available from the Assistant Secretary (Science), (4223/2), The Open University, Walton Hall, Milton Keynes MK76AA or telephone Milton Keynes (0908) 653481; there is a 24 hour answering service on 653868.

Closing date for applications: 31st October.

(9371)A

UNIVERSITY OF LEICESTER | DEPARTMENT OF ZOOLOGY

RESEARCH **ASSISTANTSHIP**

Applications are invited for the post Research Assistant at postdoctoral or graduate level to join a group working on the arrangement and expression of DNA sequences in the chromosomes of amphibians. Applicants should have some experience with recombinant DNA and related technologies. The appointment will be for one year in the first instance, commencing 1st October, 1981, but is likely to be renewable for a further 2 or 3 years. Salary scale £5,285 to £7,700.

Applications, with the names of 2 academic referees, to Professor H C Macgregor, Zoology Department, University of Leicester, Leicester LE1 7RH. Enquiries by telephone welcome (0533-554455 ext 115)

UNIVERSITY OF WARWICK

RESEARCH **ASSISTANTSHIPS**

HIGH PERFORMANCE CERAMIC ALLOYS

Applications are invited for postgraduate and postdoctoral research assistantships concerned with the development of new structural ceramic alloys within a group in the Department of Physics, led by Dr M H Lewis, supported by the Wolfson Foundation. The research has evolved from a collaborative programme with Lucas Industries in studying microstructural develop-ment, deformation and fracture mechanisms in ceramics based on the β — Si₃N₄ crystal structure.

Applicants should preferably have experience in electron-microscopy and associated microanalytical techniques or in ceramic fabrication and mechanical testing. Appointments are for 2 years from October, 1981 or as soon as possible thereafter. Starting salary either up to £6,475 pa on the Range IB scale: £5,285 — £7,700 pa or £7,700 pa on the Range IA scale: £6,070 — £10,575 pa.

Applications (no forms) should include a curriculum vitae and the names of two referees to the Academic Registrar, University of Warwick, Coventry CV4 7AL. Please quote Ref. No: 2/A/81/0. Closing date for receipt of applications 4th September, 1981.

THE INDUSTRIAL LIAISON PROGRAM OF THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY PRESENTS A COLLOQUIUM ENTITLED

"Microcapsules and Microcarriers in Biotechnology"

October 15, 1981 Date:

Professor Robert S. Langer, Jr., MIT Chairman:

Professors Marcus Karel, Alexander Klibanov, Co-Chairmen:

William Thilly, MIT Professor E. Katchalski-Katzir Other Speakers:

Weizmann Institute of Science Professor D. Papahadjopoulos University of California, San Francisco Professor T. Chang, McGill University

J. Salk, M.D., Salk Institute

MIT Kresge Auditorium, Cambridge, MA 02139 Location:

Maria Clara V. Suva Martin Contact: Industrial Liaison Program Tel: (617) 253-2691. Telex: 921473

Attendance Fee: Industrial Liaison Program (ILP) Members - free

Non-ILP Members - \$500 Immobilized Enzymes

Enzyme Stabilization

Controlled Drug Delivery Systems Liposomes — Drug Targeting Microcapsules

Diffusion Control in Food Systems Microcarriers for Mammalian Cell Culture Microcarriers in Vaccine Production

Abstract:

Topics:

Major advances have been witnessed in the past few years in the area of biotechnology, which can be defined as the application of engineering principles to biological processes. In this coloquium, the use of novel concept — microcapsules and microcarriers — in biotechnology will be discussed. These particles possess significant potential in both basic and applied research. The applications in several important areas will also be discussed including their use as (i) supports for cells which make useful products, (ii) matrices for enzymes to be used as bioproducers or bioconverters, and (iii) the central components in drug and food delivery systems (NWX793)C delivery systems.

Frontiers in Liposome Research: **Targeted Chemotherapy** November 5-7, 1981

A meeting sponsored by the Northern California Cancer Program and the School of Medicine, UC — San Francisco and organized by Dr. D. Papahadjopoulos. Will bring together a group of investigators with diverse backgrounds to critically evaluate the use of liposomes for targeted chemotherapy. Recent advances in the field will be presented as a background for discussions on the prospects for future progress and clinical trials. The meeting will be limited to 75 participants.

For additional information contact Dr. S. Szoka, School of Pharmacy, University of California at San Francisco, San Francisco, CA. 94143 USA. (NW832)C

GRANTS and SCHOLARSHIPS

IMPERIAL CANCER RESEARCH FUND Research Studentship (Bursary)

Applications are invited from recent honour graduates for a Bursary in the Transcription Laboratory to study the molecular biology of the DNA tumour virus polyoma.

The award, for full time studies leading to a higher degree (PhD) will be tenable for three years with a non-pensionable grant of £4,140 a year (subject to tax) and in some cases additional allowances. Candidates should have a first or upper second class honours degree in one of the biological sciences if they are UK graduates, but non-U.K. residents are not necessarily excluded. A strong background in molecular biology will be important and some training in recombinant DNA techniques would be particularly desirable.

For further information telephone Dr R. Kamen (01-242 0200 ext 277). Application forms are available from The Personnel Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields London WC2. Tel. as above ext 305. Completed application forms should reach the Fund no later than 1st September 1981.

THE OPEN UNIVERSITY FACULTY OF SCIENCE

J

RESEARCH FELLOWSHIP

(Brain Research Group) (Temporary)

Applications are invited for a temporary post as Research Fellow to join the Brain Research Group in the Biology Discipline at the Open University.

The successful candidate will be expected to pursue their own line of research within the interests of the Group and also to collaborate on existing projects, which include the neurochemical correlates of developmental plasticity and early learning, the role of glycoproteins in synaptogenesis and synaptic function and the development of transmitter systems.

Candidates should hold a PhD degree in biochemistry/cell biochemistry/cell biology. Experience in neurochemistry and immunology will be an advantage.

The post was first advertised in December 1980 but an appointment was not made. Applicants who replied to the original advertisement will be automatically re-considered and need not apply again.

The post is available immediately for a period of two years, with a strong possibility of renewal for a further year. Salary will be on the Research and Analogous 1A scale £6,070 - £10,575 p.a. An appointment will be made within the range £6,070 - £8,515 p.a. on the 1A scale.

Further particulars and application forms are available from the Assistant Secretary Science (4152/1), The Open University, Walton Hall, Milton Keynes MK7 6AA or telephone Milton Keynes (0908) 653481: there is a 24 hour answering service on 653868.

Closing date for applications: 7th September. (9374)E

UNIVERSITY OF ABERDEEN DEPARTMENT OF CHEMISTRY DOCTORAL

POST-DOCTORAL RESEARCH FELLOWSHIP

Applications are invited for an SRC funded Postdoctoral Research Fellowship concerned with the decomposition of alkoxy radicals in relation to fundamental aspects of unimolecular reactions and atmospheric chemistry using photolytic techniques. The post is tenable for one year working with Dr L Batt.

Salary within Range IA, £6,070 — £7,290 per annum, with appropriate placing.

Further details from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by 11 September 1981. (9378)E

UNIVERSITY OF GLASGOW INSTITUTE OF NEUROLOGICAL SCIENCES POST DOCTORAL FELLOWSHIPS (Immunology)

Two vacancies exist for Immunologists with post doctoral experience, to study auto-immune diseases of the nervous system. Candidates should have general immunological experience; an interest in tissue culture an advantage. The positions are for three years in the first instance.

Applicants should send Curriculum Vitae together with the names of three referees to: Dr P O Behan, Dept of Neurology, Institute of Neurological Sciences, Southern General Hospital, 1345 Govan Road, Glasgow G51 4TF. (9381)E

DEPARTMENT OF CHEMISTRY POSTDOCTORAL RESEARCH FELLOWSHIP IN BIOSYNTHESIS

A Fellowship is available from 1st October, 1981, renewable for a second year, for research on the biosynthesis of the polyether ionophore antibiotic monensin. The project will involve the application of C-13, H-2 and O-18 labelled precursors. Experience in organic chemistry and/or mechanistic enzymology is required.

Salary on 1A Scale within range £6,070 to £6,880 plus superannuation. Starting point dependent on age and experience.

Applications, with the names of two referees, should be sent as soon as possible to Dr J A Robinson, Department of Chemistry, University of Southampton, Highfield, Southampton SO9 5NH. Please quote ref: N. (9368)E

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY RESEARCH FELLOWSHIP

Applications invited for a Post Doctoral Research Fellow IA for a project to produce monoclonal antibodies to *Treponema pallidum*. Experience in cell culture and/or immunology would be advantageous.

The post is tenable from 1 October 1981 for 18 months.

Informal enquiries to Dr C W Penn, Department of Microbiology, (021 472 1301 ext 3673).

Salary on Research Fellow IA scale £6,070 — £10,575 plus superannuation. Maximum starting salary

Further particulars from Assistant Registrar (Sci & Eng), University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (three copies) including full curriculum vitae and naming three referees should be sent by Friday 11th September 1981. Please quote reference NM5. (9383)E

UNIVERSITY OF DUBLIN
Trinity College

POST DOCTORAL RESEARCH FELLOWSHIP MICROBIAL ECOLOGY

Applications are invited for the above post from microbiologists or botanists, to work on microbial aspects of immobilization of fertilizer nitrogen, nitrogen fixation and mobilization of insoluble N in peat under willow coppice grown for biomass fuel.

The appointment will be tenable for a period of two years, commencing on 1st October, 1981.

Salary scale: IR£5,897 — IR£6,129 per annum.

Candidates should submit *curricu-lum vitae* together with the names of two referees to:

Dr Paul Dowding, Department of Botany, Trinity College, Dublin 2

to arrive not later than 20th September, 1981. (9376)E

UNIVERSITY OF ABERDEEN DEPARTMENT OF ZOOLOGY

POST-DOCTORAL RESEARCH FELLOWSHIP IMMUNOLOGY/ ENDOCRINOLOGY

Re-Advertisement

Applications are invited for an SRC supported post-doctoral research Fellowship studying Autoimmune Destruction of Fish Gonads. The post is tenable for three years, working with Dr I G Priede and Dr L M Laird to examine this phenomenon first demonstrated on salmonids.

Salary within Range IA, £6,070 — £7,290 per annum, with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 11 September 1981. (9375)E

STUDENTSHIPS

THE POLYTECHNIC: WOLVERHAMPTON The South Staffordshire Medical Centre

Applications are invited for a

RESEARCH STUDENTSHIP

financed by the Rotha Abraham Bequest, to undertake a research project on "MICROPROCESSOR CONTROLLED REGULATION OF BLOOD GLUCOSE IN THE NEW-BORN"

Applicants should possess, or expect to possess, at least a second class honours degree in an appropriate discipline, eg biochemistry, clinical chemistry, analytical chemistry, or equivalent.

The studentship is tenable for up to two years and it is expected that the successful candidate will register for a higher degree.

Further particulars and application forms from; The Faculty of Science Office. The Polytechnic, Wulfruna Street, Wolverhampton WV11LY. (Tel; (0902) 27371). (9350) F

UNIVERSITY OF EDINBURGH DEPARTMENT OF MOLECULAR BIOLOGY POSTDOCTORAL RESEARCH FELLOW

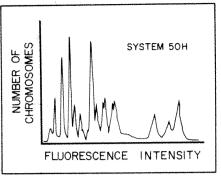

Applications are invited for a postdoctoral research fellowship in the above department for work involving the cloning of developmentally regulated MRNA sequences in Xenopus. The appointment available from 1st October 1981 will be for three years on an SERC funded research grant. Salary starting at point 3 (£6,880) on the 1A range for research and analogous staff. Candidate with directly relevant experience would be preferred, but inquiries are also invited from people who have recently completed PhD work in related fields and would like to acquire methods of nucleic acid and cloning technology. Informal inquiries may be made to Dr P Ford (031) 667 1081 ext 2873/8.

Applications should be made in writing, quoting at least two referees, to Dr P J Ford, Department of Molecular Biology, King's Buildings, Mayfield Road, Edinburgh EH9 3JR. Please quote reference 5042. (9379)E

No other commercially available cell sorter and analyzer approaches the power, precision and versatility of the Ortho Systems 30/50. The instrument is offered in two basic configurations: System 30-a high resolution, 21 parameter analytical flow cytometer, and System 50-which adds cell sorting capabilities to the System 30 flow cytometer. Both feature dual lasers as standard equipment for increased analytical power.

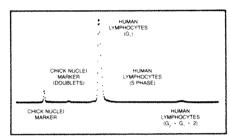

System Components

To appreciate the far-reaching capabilities of these Ortho instruments, consider that the System 50 combines: two lasers-a .8 milliwatt helium-neon for ultra high precision scatter measurements and a 5 watt argon type for fluorescence measurements (optional argon-ion, and krypton-ion lasers with U.V. capability are available); four detectors-two of the photo-multiplier type for right angle scatter, and fluorescent emission detection (S-20 response, 185 nm-850 nm), and two solid state sensors for axial light loss and narrow angle forward scatter: a sophisticated optical system incorporating fiber optics: a multiplexed multichannel analyzer, with C.R.T. display: the signal processor unit: and an advanced cell sorter module. Additionally, the Model 2150 computerized 8 parameter data handler/sorter controller is available as an option* The 2150 System features

2. Histogram of CHO chromosomes stained for D.N.A. Ethidium Bromide/Chromomycin Av

Cytofluorograph System 50H Laser-250mw @ 457nm. Red Fluorescence

2. Histogram of human lymphocytes utilizing a chick nuclei marker for standardization and stained for D.N.A. with Propidium Iodide. C.V. = 1.65% (Human Lymphocytes)

simultaneous data acquisition, and real time processing while sorting is in progress.

System Capabilities

Together, these modules allow the System 50 to provide and analyze morphological information—a significant first for a flow cytometric instrument. With four detectors and the ability to display pulse height, pulse area or pulse width analysis for each—a total of 21 distinct measurement parameters can be studied

The System 50 also features: two bidimensional regions of interest, dual histogram multi-channel analyzer with cytogram mode, super-sil quartz optics with which the cells are analyzed and easy sample entry.

In order to provide customers with complete support. Ortho maintains an Applications Laboratory that is available for confirmation and consultation services. Additionally, an international network of service technicians is ready to aid customers should calibration or repairs ever be required.

Remarkable Results

The histograms and cytograms displayed were produced by the System 50. Evaluate them. And consider the difficulty of deriving this data by any other means. The capabilities of this unique Ortho instrument will speak for themselves.

State-of-the-art cell sorting and analysis from Ortho The Cytofluorograf Systems 30/50

ilson has something new and better in pumps. It's our new Model 302 microprocessor-controlled pump. Model 302 offers this unique combination of capabilities for HPLC and preparative chromatography: (a)

microprocessor control

(b) effective flow rate range of 0.005 to 100 ml/minute with pressures to 6,000 psi (c) both flow and dispense modes (d) four easily interchangeable heads for analytical, high pressure, preparative, and recycling preparative LC.

There's so much you can do. Interface with a computer and automate your LC procedures. Prepare gradient programs. Dispense repetitively, either fixed or varied volume aliquots. Control flow rates with high accuracy.

Make this pump the heart of your LC system. Your inquiry will not only bring details on this remarkable pump but also on other fine Gilson instruments for LC and HPLC. Contact:

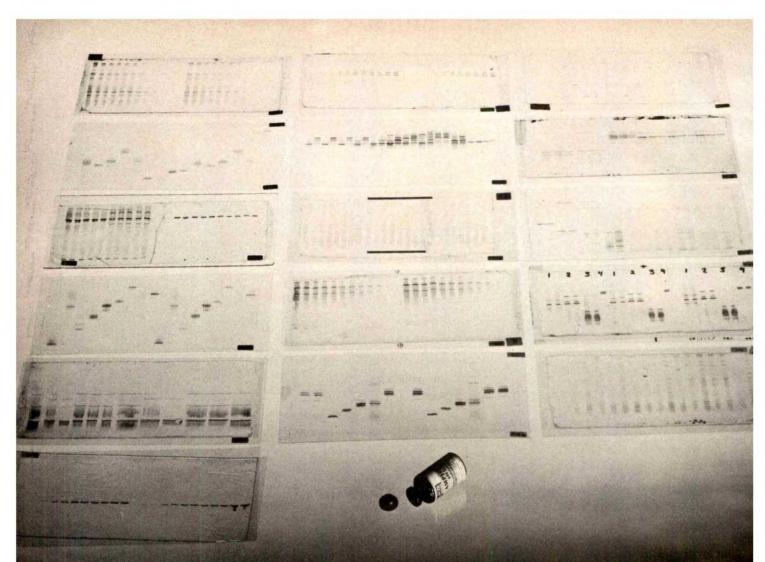

Gilson Medical Electronics
Box 27 • Middleton • WI 53562 • U.S.A. • Telephone (608) 836-1551

Gilson Medical Electronics (France) S.A. B.P. No. 45, 95400 • Villiers-le-Bel, France • Telephone 990.54.41

When the warranty runs out, Gilson won't run out on you.

ACETYLCHOLINE RECEPTOR CLUSTERS

The samples you can analyze with half a bottle of Ampholine

Cut your electrofocusing costs to a fraction of previous levels without sacrificing quality or resolution. Save substantial time casting, running, and staining gels as well. High performance electrofocusing lets you analyze well over 600 samples per bottle of Ampholine. And if you're struggling with an especially tight budget this year, we can help you save even more. High performance gels are cast by capillary action onto thin plastic support foils in layers a mere 0.5 to 0.25 mm thick. Because the new thin gels are cooled more efficiently, resolution-robbing thermal gradients are eliminated while run times drop to as little as 30 minutes.

Ampholine, the LKB tradename for the world's largest selling carrier ampholyte, is now available in four new pH ranges. The new ranges are specially preblended for direct use in either acrylamide or our new agarose gels and exhibit excellent conductivity and reproducibility. By switching

to our new preblends, you'll save preparation time and reduce your stocking costs as well.

High performance electrofocusing is just one of a series of new and improved techniques you can perform on the Multiphor System. For more details about this and other new kits soon to be released, contact your local LKB representative. We have offices everywhere. Or phone us today at one of the addresses listed below.

WHY BUY MONOCLONALS FROM THE PRIDIOCHEMICALS COMPANY?

1. HIGH STANDARDS

Making biologically active radiochemicals for research requires a company-wide quality control discipline of the strictest kind.

2. VALUABLE RESOURCES

Our large, multi-disciplined staff assures you of thoroughly evaluated, carefully specified, state-of-the-art monoclonal antibodies.

3. EXTRA SERVICES

There are many, from technical consultation with our staff to documented assay results included with each shipment.

4. WIDE SELECTION

Our current offering of monoclonal antibodies has been selected in response to your research needs and requests. New monoclonals will be introduced continuously to meet these needs.

= Biotechnology &

One of the most promising applications of modern interdisciplinary science.

"Biotechnology - A Comprehensive Treatise in 8 Volumes" is the title of what will be the first complete reference work of this expanding discipline.

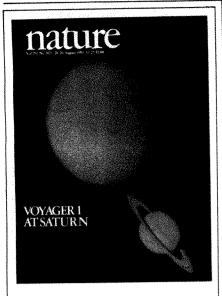

Activities in biotechnology have increased significantly in recent years both in research and development. Industrial applications in many areas show great promise in providing much needed products that would otherwise be difficult or even impossible to obtain. In addition, biotechnological methods play an important part in helping to reduce environmental pollution.

In view of the advances that have been made an encyclopedic description of the state of the art in this field is both needed and timely. It will provide the basis for further applications of present knowledge and for the generation of new knowledge through extended research efforts. A descriptive brochure and a 16 page sample chapter are available to inform you more fully about this exciting project.

To obtain this material, please complete and mail the information coupon today.

Please complete and return to Verlag Chemie GmbH, Marketing Dept. P.O.Box 1260/1280, D 6940 Weinheim, Federal Republic of Gerr

MOLECULAR ORIGINS AND EVOLUTION **PHOTOSYNTHESIS**

A special issue of BioSystems (Vol. 14, No. 1)

Contents

Foreword, H. Baltscheffsky.

Models for protocellular photophosphorylation, P.R. Bahn and S. W. Fox.

Prebiotic photosynthetic reactions, G. J. F. Chittenden and A.W. Schwartz.

The formation of chromophores through amino acid thermolysis and their possible role as prebiotic photoreceptors, B. Heinz and W. Reid.

Phase separation, charge separation and biogenesis, H.J. Morowitz.

Stepwise molecular evolution of bacterial photosynthetic energy conversion, H. Baltscheffsky.

Metalloproteins in the evolution of photosynthesis.

R. Cammack, K. K. Rao and D. O. Hall. Evolution of uphill electron transfer, A. A. Krasnovsky.

Evolution of photosynthetic reaction centers, J.M. Olson.

H⁺ transport in the evolution of photosynthesis, J. A. Raven and F. A. Smith.

The coupling ATPase complex: An evolutionary view. D. A. Harris.

Evolution of the control of pigment and plastid development in photosynthetic organisms, J. A. Schiff. Announcement.

Date of publication: August 1981. Price: US\$30.00 including postage. All orders from individuals must be prepaid.

More trouble for the hapless shuttle

Ironically, the shuttle device for putting objects into orbits about the Earth is being threatened now by commercial as well as technical problems (see page 789). After a decade of planning, much of it imaginative and some of it over-imaginative, it now appears that the shuttle may not be able to hold its own commercially with other means of launching satellites. The European rocket Ariane appears, in the short run at least, to be able to offer launching facilities more cheaply than comparable rocket systems in the United States, and there is at least a possibility that the shuttle itself will not be much cheaper (see page 789). In any case, the shuttle is so far behind schedule, and demands from the Pentagon on its services so clamant, that it may be some time before the device is able to perform the general service for which it was designed - making sure that the world is well supplied with telecommunications satellites (on which it is now dependent), assisting with the exploration of the Solar System and the regions beyond and giving all of us the sense that space, as we have learned to call it, is part of our domain. The irony is, of course, that the shuttle, intended as a way of cheapening the launching of satellites, should appear to be threatened by an upstart competitor from Europe. Especially in France, people will be recalling the legend of David and Goliath. The snag is that, in the end, we shall all be losers.

A device such as the shuttle (intended to have its second trial flight next month) is not merely desirable but essential. When the National Aeronautics and Space Administration decided, at the end of the Apollo programme, that sending a man to Mars would be a less useful application of the skills that it had acquired than the building of a reusable launching system, it took the right decision. Better to go step by step than to hunt for yet another worldwide television hook-up. But the shuttle, as it has been developed, is something of a bastard. The original conception of a launching device that could be used over and over again has been adulterated by arranging that the largest items of equipment, the launching rockets, should fall into the sea and be lost. Some time in the coming decade, after the system as it stands has proved itself, attention may be turned again to the recovery of these items. In the meantime, there is a serious danger that the shuttle will limp along, working principally for the military, and that the usefulness of Earth satellites will be denied.

In all the circumstances, it is necessary that the space administration, or perhaps even the US Congress, should stand back from the problems that now afflict the shuttle and ask where, in the end, it is meant to go. The issues that must be settled are not simple, but neither are they beyond comprehension.

First, there is a case for asking whether the present concept of the shuttle, as embodied in the spacecraft called "Columbia", is the most appropriate, given what has been learned in the past ten years; if it is not, the space administration (or Congress) should be prepared to write off the huge expenditures of the past decade, and to start again. Such a question could be settled only after a careful technical enquiry, but this is the time at which to make it. Second, there should be a more sober appraisal than there has been so far of the utility of being able to put satellites into orbits — a futuristic appraisal of the market. For the past several years, telecommunications authorities have been assuming that there will always be some way of launching their relay stations, and that the cost will be a small part of the cost of providing them with signals; in present circumstances, in which the benefits of terrestrial switching circuits are only just becoming clear, is that assumption still valid? And, since it would be not merely a black mark for the shuttle project but an international tragedy that the Large Space Telescope should not be launched, or not launched more or less on time, how should such projects be organized? Finally, there are questions about the future, and of several kinds. Do the difficulties that have afflicted the shuttle in

the past few years imply that it has been discovered empirically — the hard way — that even the United States is no longer capable of everything? What in the medium term, say by the end of the century, is the utility of the Earth orbit? Science and the Pentagon apart, telecommunications will have to bear the burden. And what of the more distant future? Science fiction, which has a habit of becoming fact, would suggest that the time will come when people will think it intolerable that they should be prevented by the lack of facilities from going where they choose. Such conceits, always infuriating for those concerned with next year's budget, are nevertheless historically (so far) undeniable.

Agony in London

Whom the gods would destroy, they first make seem ineffectual. This seems to be the underlying trouble at the University of London, which has just been through the traumatic process of dividing the public grant for the present academic year (which began financially on 1 August) among its several schools and specialized institutions. But the university, which is a microcosm of the British university system as a whole, is not entirely to blame. Both the university and the University Grants Committee earlier in the year were faced with an impossible task that of saving large amounts of money so quickly that they could not properly take account of academic and educational considerations. Solomon himself would have been hard pressed to make an equitable division of the diminished budget. Yet both the university and the grants committee have responded with delay. The grants committee let its dependants known only on the eve of the academic year what they would have to spend in the three succeeding years. The University of London, in which financial decisions are delegated to a body called the Court, has delayed a further six weeks and has announced financial allocations (Nature, 20 August) which are inconsistent both with the principles laid down by the grants committee and with the interim recommendations of the committee (under Sir Peter Swinnerton-Dyer) which the university had set up to suggest how its organization might be adapted to much smaller budgets.

What has happened, and is about to happen, at the University of London is important because it is among the most important of the universities in the United Kingdom. It has more students than any other British university, and is comparable in size with the Berkeley campus of the University of California. The university is the largest single source of physicians in the United Kingdom, but also has specialized institutions for training architects, veterinarians, pharmacists and even agriculturalists. Constitutionally, however, the university is not an integrated whole but an agglomeration of titularly autonomous institutions so loosely held together that they are a federation on the Canadian pattern, not that of the United States. The separate institutions include a dozen medical schools (soon to be fewer), internationally known centres of teaching and scholarship such as the London School of Economics and Imperial College, a host of graduate institutions (not only medical) whose importance nationally and internationally is beyond dispute and no fewer than eight more general colleges, scattered over twenty-five miles, which differ in size, the pattern of courses offered to undergraduates and their reputations in research. The question now is whether last week's decision by the Court will have

irreparably damaged the character of this remarkable, if anomalous, institution.

On at least three counts, the Court's decisions cannot fail to cast a long shadow over the university. First, the Court seems meekly to have accepted the grants committee's edict that the proportion of students (graduates and undergraduates) following science courses should be reduced by 11.3 per cent by the academic year beginning in 1983. This is a sharper contraction than the intended reduction of the British university student population as a whole and much sharper than the planned contraction of science teaching — a mere 2.2. per cent throughout the United Kingdom. Taking the wording of the grants committee's letter literally, however, the Court of the university has decided that teaching in the physical sciences should be maintained, and has gone on to plan for a reduction of 28 per cent in the numbers of students following courses in biology. The grants committee's recommendation that special consideration should be given to biology courses of "potential economic importance" (another name for biotechnology?) seems not everywhere to have been heeded. The result, by 1983, is likely to be that most departments of "soft" biology in the university will have shrunk to such a size that they are no longer viable. In the meantime, most of them will no doubt whistle hard to keep their spirits up and will admit more students in the next few days than prudence would dictate.

The second change of pattern now decreed that will prejudice the educational work of the university as a whole is the Court's decree that undergraduate courses in which two principal subjects are combined should bear the brunt of the contraction. To be fair, the Court has not dreamed up this conclusion of its own accord, but instead has asked the grants committee for "guidance". Having been told of what was plainly an afterthought by the committee, the court has done its arithmetic accordingly. At no point has it been considered whether these decisions are educationally desirable. Yet there are several schools within the university where combined courses of this kind, involving both general and particular studies, are much valued by employers, not to mention students. In any case, when it is plain that one of the faults of the British university system is that it offers too specialized an education to most undergraduates, by what right does the grants committee recommend that the efforts made in London to put that balance right should be negated? The Court says in its letter to its pensioners that "the far-reaching implications of this [decision] will have to be examined within the university". The snag is that its financial decisions for the coming year will have preempted sensible discussion.

Third, the allocations of funds from the university budget of £157 million for the coming year must put the survival of many of the smaller schools of the university in jeopardy. The difficulty is that institutions whose costs consist largely of salaries for academic and ancillary staffs - often three-quarters of the total - cannot hope to live within the shorter commons now decreed by getting rid of staff, for contracts of employment often require that notice of dismissal should be given before the beginning of an academic year. So how will such places manage? Especially in those schools where the numbers of students from overseas has fallen sharply, the outlook must be grim. Yet the Court of the university promises nothing in the way of help. Instead it hopes that the "cost of contraction" can be met "from some special source" and mentions the £20 million the Universty Grants Committee set aside last year to meet the cost of academic redundancy. On present form, the true cost will be far greater.

For other than financial reasons, this is an awkward time for the university. The Vice-Chancellor, Lord Annan, is about to be succeeded (on 1 September) by Professor Randolph Quirk. The senate of the university, responsible for academic policy, has just been reconstituted and will not be meeting until November. The new management has a daunting task ahead of it. It will also have an awkward constitutional problem to tackle. The Court of the university is charged with making final decisions of the distribution of funds but is barred from making decisions with academic implications without consulting the academic senate. The past few weeks have shown is that, at a time of rapid

contraction, the notion that academic and financial considerations can be cleanly separated is a fiction. But so it must be even in good times. The isolation of the Court's proceedings from the rest of the university, which has made a nonsense of the committee on academic organization, should not continue.

The university must recognize that the looseness of its constitution is increasingly an encumbrance. In spite of the committees which occupy a substantial part of many academics' time, the educational policy of the university is an amalgam of the separate decisions of individual schools. That it could or should be otherwise at places such as the London School of Economics or at Imperial College is unthinkable, but in the university as a whole, the result is inevitably duplication and incoherence. If it had the time, a stronger university might be able to create a pattern that makes more sense. But even in the short run, a stronger university could help deal with the most urgent problem — the future of academic staff. For it would be thoroughly anomalous if some parts of the university found themselves firing, or retiring prematurely, academics who might be usefully employed elsewhere within the university. And it is inequitable that the people who will be put out of work should be those who happen to be employed at schools which have been hard hit, either by the disappearance of overseas students or by the decisions forced on the Court by the arithmetic of penury — and the last-minute guidance from the grants committee.

Year of the Medfly

Californians (many of whom are ethnically Chinese) may remember 1981 as the "year of the Medfly". With a little luck, they may also come to think of 1981 as a year in which the innocence of those who pretend that nature is never malevolent was made to fade away.

The Medfly is an aphid, and its name is arrived at by a shortening of "Mediterranean". It will probably never be possible to tell how the fly reached California or the importance, in the infestation of the past few weeks, of the supposed infertility of the supposedly sterile males released by the state government into the wild. With the winter (such as it is) soon to come, Californians will with reason be hoping that most, perhaps all, of this exotic species will be killed off, and that that will be an end of the affair. Most fruit farmers will be worse off, some may even have been made bankrupt, but life will go on, on Sunset Boulevard and elsewhere.

Unfortunately, the truth is different. Aphids are pests and the stringent quarantine regulations in the United States that prohibit the unchecked importation of citrus fruit make the United States especially vulnerable to unfamiliar pests such as the Medfly. One concomitant of policies based on quarantine is that the consequences of a breakdown must be draconian. In Britain, for example, where vaccination against foot-and-mouth disease is not practised, infected animals must be slaughtered; and potential harbingers of rabies must be kept in isolation for six months. In California, the recognition of the first Medfly should have been followed by a vigorous attempt at its eradication.

Governor Jerry Brown was, by all yardsticks, slow to come to this conclusion. Everybody will sympathize, although not everybody will condone. In many ways, it is admirable that California should have taken the lead, over many years, in the protection of its own delectable environment. Governor Brown himself, one of the torch-bearers, has benefited politically as a result. Much of what has been done in California to reduce the concentration of nitric and nitrous oxides in the atmosphere has cost a great deal of money, but somehow the state (and Mr Brown) has scraped along. The trouble with the Medfly is that it has challenged the governor in a way that could not fail to be politically embarrasing. Nobody who wants to stay in Sacramento can, with an easy conscience, order out the spray guns. So the Medfly has prospered. It would be sad if Governor Brown's fortunes, as a result, went into decline.

Biotechnology's first casualty — so far

DNA Science left out on a limb

Washington

E.F. Hutton, one of Wall Street's leading investment houses, is having second thoughts about its involvement in recombinant DNA research. Earlier this month the company backed out of a deal it had set up which would have used money from over 40 institutional investors to support academic research in both US and foreign laboratories. Now it is talking of an alternative, less ambitious scheme exploiting recent changes in tax legislation to sell genetic engineering research as an attractive tax shelter.

The initial plan, first announced in February of this year, was to channel investment funds to scientists through a company set up by Hutton called DNA Science. The centrepiece of this scheme was an agreement with the Weizmann Institute of Science in Israel for collaboration on research projects. Weizmann would have provided the molecular biologists and DNA Science the chemistry through Nobel laureate Dr Christian B. Anfinsen, appointed chief scientist of an Israeli subsidiary called Taglit.

According to Hutton, the deal fell apart when the investment company began to have doubts about the legal propriety of mixing "passive" and "active" investors, some merely seeking a financial return, others demanding a greater involvement. The potential conflict between these goals surfaced when one proposed investor, Johnson and Johnson, began negotiating for exclusive marketing rights to any products which resulted from DNA Science-financed research.

Failure to reach agreement before a target date stipulated in the publicly-distributed prospectus, by which \$40 million was to have been raised, meant that Hutton was required to return the money it had already collected from outside investors. But the debate over the appropriate form of involvement by investors also reflects growing concerns that the potential commercial benefits of genetic engineering may have been oversold.

In addition to dropping the Weizmann deal, which would have focused largely on interferon, other proposals now being reassessed include an arrangement with the Battelle Memorial Institute in Columbus, Ohio, for research into projects such as the use of microorganisms to degrade toxic wastes, and collaboration with Dr John Baxter of the University of California

in San Francisco.

Dr Harsanyi, vice-president of DNA Science, says the company will now concentrate on putting together individual projects or "packages of projects" for separate funding by groups of investors, rather than trying to raise the initial capital in one lump. This means shifting the focus from long-range research to projects with more clearly-defined commercial goals.

Exploiting the tax haven incentives offered by research and development financing that were recently increased by the federal government will exclude some of the original investors, such as pension funds, which already enjoy significant tax concessions.

Ironically Hutton was one of the first major financial houses to promote the long-range commercial potential of recombinant DNA research. Nelson M. Schneider, a pharmaceutical analyst with the company who is credited as the principal architect of DNA Science and is now one of its vice-presidents, reported to a congressional committee in June that, if present trends continue, by 1985 private companies could be putting as much into biomedical research as are the National Institutes of Health (NIH).

Under the scheme unveiled in February, which had been suggested as a model for university/industry collaboration in supporting recombinant DNA research,

DNA Science would have set up a number of small "daughter companies" near university campuses in which university staff could apply themselves to commercially-oriented research while maintaining their campus links.

This was to have been the arrangement with the Weizmann Institute under an agreement reached with the institute's commercial arm, the Yeda Research and Development Corporation. Dr Anfinsen said last week that he had resigned from his post as head of the laboratory of chemical biology at the NIH's National Institute of Arthritis, Metabolism and Digestive Diseases to take up the Israeli position with DNA Science. He said that he was waiting to see what happened at the Weizmann Institute, which might continue working in the same direction on its own, before deciding what to do next.

DNA Science officials are confident that much of their work in finding both investors and research projects needing support can be salvaged. Dr Harsanyi says that several university groups have approached Hutton, interested in exploiting their research, but reluctant to become involved in the commercial management of their results. DNA Science is offering to take on this management responsibility, which could include finding potential customers for products.

David Dickson

CERN declares peace with the locals

The 26-km circumference large electron-positron ring (LEP) proposed for construction at CERN near Geneva seems to be steering itself successfully among the several political shoals that surround the project. The lastest development is that CERN and the most active environmental opposition group, Agena, have issued a mollifying joint statement.

Agena, which includes a local mayor among its six members, was successful in halting work on a reconnaissance gallery by means of a legal technicality. It has also been active in canvassing support against LEP within the Jura region of France, so any degree of rapprochement between Agena and CERN is significant.

In the statement, Agena says it is concerned about LEP polluting water and the air, and about LEP's possible effect of reducing employment at CERN (to help pay for the project). Agena asks that CERN should adopt a "different approach" and give local people time to express their opinions on the project.

For its part, CERN promises to consult all relevant associations and trade unions in "an atmosphere of cooperation"; says that it "understands" Agena's fears; that anyone is free to speak to CERN and its director-general, Professor Herwig Schopper, and that no work will be done until an environmental impact statement is complete, and the French and Swiss authorities have been given time to react through the normal national channels providing planning permission.

This latter move is an important step for CERN — although Schopper proposed it at the June meeting of CERN Council, well before the joint statement with Agena. Legally, CERN is an international organization which officially needs to deal only with the foreign ministries of member and host states. But construction of LEP, reaching deep into French and Swiss territory far from the original CERN site, has occasioned new rules.

The principal step is the production of an environmental impact statement for the French Ministry of Research and Technology, the Ministry of Environment and the Ministry of External Relations in October. Then, under French law, a commission of inquiry will be set up which will assess local opinion and invite witnesses (including, presumably, Agena itself). The commission will report, and finally a decision will be taken either by the local préfet of the département or the Conseil d'Etat. This process could take until March 1982. Swiss law is less exacting, but the French process is likely to be longer.

Meanwhile, the French research ministry

is taking steps to unblock the restraint on the LEP reconnaissance gallery, which depends on whether the gallery is a temporary or a permanent construction. If it is temporary, the law under which permission was originally granted is appropriate; if permanent — as Agena successfully argued — it is not. The ministry is attempting on the one hand to argue that the gallery is, after all, temporary and on the other to get approval through a different law. Robert Walgate

Particle physics

Director resigns

Washington

Dr George Vineyard, director of the Brookhaven National Laboratory on Long Island, New York State, announced last week that he is stepping down in order to return to full-time research. His resignation has been accepted "with regret" by the board of trustees of Associated Universities Inc., the consortium of nine universities which operates the Brookhaven Laboratory for the US Department of Energy. In a statement issued after the board's meeting last Monday, Dr Vineyard said that after nine years as director of Brookhaven, where he has been since 1954, "this appeared to be a good time to make the move".

His resignation has, however, inevitably been linked to growing speculation that the Reagan Administration is contemplating cutting funds for further development work on Brookhaven's planned 400 × 400 GeV intersecting storage accelerator (ISABELLE) which is facing delays and cost over-runs.

Uncertainty over the fate of ISABELLE has been growing ever since the laboratory encountered serious difficulties in developing the superconducting magnets, 1,100 of which will be required to complete the accelerator's two-mile circumference ring (*Nature* 286, 435; 1980).

Brookhaven now says that the problems with the magnets seem to have been solved with a new design, but the delays have inevitably resulted in cost over-runs. The bill for ISABELLE is now put at \$500 million, compared with an original estimate of \$420 million, and completion is now expected in 1988 rather than 1986.

Given the intense competition from the new proton-antiproton collider under construction at CERN in Geneva, which is now likely to beat ISABELLE to one of its principal goals, the discovery of weak vector bosons, those responsible for ISABELLE face a daunting task in maintaining political support for their machine.

Dr Vineyard denies that his resignation has anything to do with the problems with ISABELLE, pointing out that the accelerator has "turned the corner by overcoming technical difficulties with the superconducting magnets". He says that other research at the laboratory is in a healthy state, and that the new national synchroton light source is about to go into operation.

The Reagan Administration has, however, been making lukewarm noises about continued support. A meeting between the High Energy Physics Advisory Panel and the National Science Foundation next month is likely to discuss options. One is a scaled-down design, using superconducting magnets which have already been constructed at the Fermi National Laboratory but produce a slightly lower field that would mean a lower luminosity. Another is to scrap ISABELLE altogether. The Administration is awaiting the outcome of this meeting before deciding whether to go on as planned, or adopt one of these alternatives.

David Dickson

Incoherent scatter radar

Auroral visions

A new high-power radar facility, designed to study the Earth's upper atmosphere and magnetosphere at auroral latitudes, was inaugurated by the King of Sweden on 26 August. The £13 million radar's operation will be supervized by the European Incoherent Scatter Association (EISCAT) whose headquarters are in Kiruna, Sweden. The director of the association is Tor Hagfors.

The member countries of EISCAT are West Germany, France, the United Kingdom (each contributing 25 per cent to the capital and running costs), Sweden, Norway (both 10 per cent) and Finland (5 per cent). Half the working time of the facility will be spent collecting data for common use. For the remainder, each country will have control of the facility for a time proportional to its financial contribution.

The radar was originally scheduled to start operation in 1978 but was delayed due to a faulty klystron — a vital transmitter component which turned out to be more difficult to develop than expected. The delay must have proved particularly frustrating to those itching to make their reputations with the new facility, but EISCAT's twenty or so staff have spent the time making astronomical observations with the receivers and developing computer software.

The facility consists of two radar systems, one operating at VHF (224 MHz) which is expected to be ready by next year, and a tristatic UHF (933 MHz) system with a transmitter/receiver at Tromso, Norway, and receivers at Kiruna and Sodankyla, Finland. The UHF system has already produced its first crop of data. The combined systems will be able to monitor the atmosphere from 50 to 3,000 km.

The incoherent scatter technique, which EISCAT's radar utilizes, exploits the fact

Deadline missed

Legislation to bring Britain into line with the European Commission's directive on the notification of new chemicals will not now be enacted before the 18 September deadline. The Health and Safety Executive acknowledged this week that too many problems still remain to be ironed out. And in any case, Parliament will not reconvene until October.

The executive is not, however, worried that the commission will take proceedings against the United Kingdom — the United Kingdom is not the only laggard. One source of confusion is that the European directive requires the compliance not merely of governments but of other corporate bodies, including commercial companies, which may find that after 18 September they are bound by the directive.

The commission is planning to publish in the near future an inventory of all chemicals at present manufactured and sold in Europe. Companies will have nine months from the date of publication to tell the commission of substances not on the list. After that, new substances will have to be tested (toxicologically and otherwise) in accordance with the directive. Until then, however, the British and other European parliaments will have a breathing space in which to find time to comply.

Judy Redfearn

that radio waves can be scattered off individual electrons and off density variations caused by plasma waves in the ionosphere. This region of the atmosphere, which is ionized by solar and cosmic radiation, extends upwards from 50 km or so. The spectrum of backscattered radio pulses can be analysed to reveal a surprisingly large number of atmospheric parameters such as electron and ion densities, ion composition, electric fields, neutral and ionized wind velocities and temperatures.

Several incoherent scatter facilities have been constructed in the past, the most powerful being at Arecibo in Puerto Rico. Only one has operated at auroral latitudes, that at Chatanika in Alaska, which is itself to be moved to Greenland to allow more effective collaboration with EISCAT. The auroral zone is particularly important to those interested in solar-terrestrial relations because it is here that those relations are most manifest. For example, charged particles ejected from the Sun during solar disturbances can be trapped in the Earth's magnetosphere and may eventually spiral down the Earth's magnetic field lines to precipitate into the auroral upper atmosphere, causing heating and intense electric currents. EISCAT's sensitive radar should allow a detailed picture of such events to be developed, particularly when used in conjunction with other ground, rocket and satellite based Philip Campbell experiments.

Soviet academics

Three deprived

Three Soviet Jewish refusnik scientists have recently been deprived of their higher degrees, apparently as a result of their wish to emigrate to Israel. They are Aleksandr Paritskii, a Candidate of Technical Sciences, formerly employed at the Khar'kov Institute of Metrology on the design of high-precision ultrasonic ranging devices; Valerii Soifer, from Moscow, a Candidate of Biology, specializing in plant mutagenesis; and Mikhail Fuks-Rabinovich of Moscow, a meteorologist.

Paritskii and Soifer, who applied to go to Israel in 1976 and 1977 respectively, were refused permission on the grounds of the "secrecy" of their former employment. The reason that Fuks-Rabinovich did not receive his visa is unknown.

Higher degrees — those of "Candidate" (roughly equivalent to a PhD) and "Doctor" (which normally requires a minimum of ten years further research) — are not, in the Soviet Union, conferred by individual universities, but are instead awarded by a special all-union body, the Higher Attestation Commission (Vysshaya Attestatsionnaya Komissiya; VAK).

Originally VAK came under the Ministry of Higher and Specialized Secondary Education, but was transferred in 1974 to the control of the Council of Ministers by a resolution of the Central Committee of the Communist Party and the Council of Ministers of the Soviet Union. This involved what the chairman of VAK, Professor V.G. Kirillov-Ugryumov, described as "qualitative changes". In particular, he said, the new regulations required postulants for a higher degree to 'combine a profound professional knowledge with a mastery of Marxist-Leninist theory and with the convictions of an active builder of communist society".

Jews who wish to emigrate to Israel clearly do not show such "convictions", but so far the Soviet establishment has been content to expel them from professional employment. The new regulations came into force on 1 January 1976, by which time Paritskii, Soifer and Fuks-Rabinovich had presumably all obtained their Candidates' degrees. Until now there had been no suggestion that the regulation should be made retroactive.

From a practical point of view, the loss of their Candidates' degrees should make no difference to the three scientists. Indeed, the change could even benefit them, since several refusnik scientists have been unable to keep menial jobs which they took to try and support themselves, finding themselves sacked because they were "over-qualified", some facing charges of "parasitism" (being without visible means of support). However, from the point of view of Soviet academic life at large, their deprivation sets what could be a dangerous precedent.

Space economics

Ariane gets an edge

Washington

The fledgling European space industry has scored its first success in the American market. Southern Pacific Communications (SPC), a San Francisco company, has selected the European Space Agency's Ariane rocket for launching its first telecommunications satellites in preference to the Delta launcher of the National Aeronautics and Space Administration (NASA).

Two satellites will be launched for SPC in 1984, which will rent out transponders on the satellites to cable television companies. The deal is a boost for Arianespace, the French-based company which will take over responsibility for the commercial operations of Ariane when the test flights have been completed.

SPC is the first US company to make a firm agreement to use Ariane, although according to Arianespace officials reservations have been made by Western Union, RCA and Satellite Television Corporation and preliminary negotiations have started with GTE. Intelsat, the international telecommunications organization, has signed up for Ariane launches for three of its next series of satellites, due to be placed in orbit next year.

The major attraction seems to be the price. Arianespace is offering extremely favourable terms for a launch, including a requirement that only 20 per cent of the launch price—thought to be about \$40 million for the SPC satellites—need be paid before the launch, with the remainder spread over the following five years.

Officials with the Grumman Corporation, which is acting as the marketing agent for Arianespace, are also making the most of continuing delays that are expected in the initial schedule for launches by NASA's space shuttle. An advertisement placed in the US press shortly after the successful third launch of Ariane from French Guiana in late June lists among the advantages of conventional launchers "well known technology and firm dates for operational customers".

The deal with SPC reflects the growing problems that NASA faces in putting the space shuttle into operational service. Already budget restrictions and various technical difficulties have forced the agency to cut the number of flights planned in the first five years of operation from 48 to 34. Priority in scheduling these early flights is being given to the Department of Defense, requiring several commercial companies either to delay their launches or seek more conventional launches.

Intelsat, which had initially planned to launch its next series of satellites from the shuttle, chose Ariane rather than the Atlas Centaur launcher primarily because of cost. Now SPC, which is eager to tap the rapidly burgeoning field of cable television — and has already sold all the transponders on its first satellite — has selected Ariane also on

cost grounds.

NASA, not surprisingly, is not too happy with these developments. Although accepting what it sees as fair competition from the European space industry, some officials in the agency feel that the generous financing terms being offered represent a government-backed subsidy which they are unable to provide.

But the agency has enough problems of its own to worry about in getting the shuttle into full operation. There is now talk of projected cost over-runs in the shuttle programme next year of up to \$500 million, which could have a significant impact on several of NASA's activities

One way of absorbing some of these costs, if the Administration does not come up with additional funds, would be to make still further reductions in the initial launch schedule, cuts which would again fall most heavily on commercial customers. Another would be to make deeper cuts in the space science programme, perhaps delaying or even cancelling the Galileo mission to Jupiter, scheduled for 1986.

With the White House talking of further substantial reductions in public expenditure next year, NASA's prospects look bleak. None of this augurs well for the International Solar Polar Mission (ISPM), planned jointly with the European Space Agency. Congress is still debating whether to replace funds for the spacecraft which the United States is contributing to the two-vehicle mission, which was axed by the Reagan Administration in March.

Publicly NASA officials are continuing to express enthusiasm about maintaining the US involvement in the mission. But internal budget proposals sent up to NASA administrator James Beggs for the next year are said not to include any funds for the ISPM spacecraft (nor for a mission to Halley's comet, now being pushed as a sample-return mission to distinguish it from the European Space Agency's Giotto programme). This could change before the final budget proposals are agreed to either by the NASA hierarchy or with the Office of Management and Budget; but nobody is David Dickson being too optimistic.

Judy Redfearn adds:

Arianespace says that potential customers have been heartened by the success of the test flight from Kourou, French Guiana, in June. Those already holding launch reservations are apparently beginning to negotiate term contracts. One official guesses that three of the 14 reservations now on the books will be made firm by the end of December. The Ariane rocket will put a satellite into geostationary orbit for between \$27 and \$28 million. Thor Delta launches now cost up to \$7 million more. The attractions of the shuttle. originally estimated to cost between \$15 and \$16 million per launch, have diminished with the uncertainty about the project and the threat that the cost will increase by more than half in 1985 and perhaps by three times that.

Deep sea research

Watery grave?

Washington

In a compromise designed to meet conflicting pressures on oceanographic research, the National Science Foundation (NSF) has decided to incorporate its current Deep Sea Drilling Project (DSDP) into its new Ocean Margin Drilling Program (OMDP), the latter to be financed jointly with the oil industry using the drilling ship Glomar Explorer to investigate the geology of the ocean bed.

The decision will mean phasing out Glomar Challenger, the ship from which DSDP currently operates. Several scientific goals of the programmes will continue in drilling from the Explorer. To accommodate them, part of Explorer's own research programme, to be directed at the ocean margins beyond the edge of the continental shelf, will be delayed.

NSF officials hope that by combining the two programmes they will significantly reduce the total costs of scientific ocean drilling programmes and provide a "realistic framework" within which both can be pursued. In addition to the financial advantages, they concede that the decision should reduce some of the friction that had been caused by the scientific community's concern that commercial goals would squeeze out scientific objectives.

Ten oil companies have so far agreed in principle to contribute towards the costs of the Ocean Margin Drilling Program, announced last year by NSF as a jointly-funded venture (*Nature* 283, 321; 1980). The project had been enthusiastically promoted by the Office of Science and Technology Policy as a model for future collaboration between the public and the private sector.

Many scientists, however, feared that too much of the OMDP activity would be concentrated on areas of the ocean floor of greater interest to the oil industry than to the academic community; also that the series of experiments currently being conducted from Glomar Challenger, which can drill holes more cheaply and quickly but is more restricted in its performance, than Glomar Explorer, would be brought to a premature conclusion.

Dr John Slaughter, director of NSF, has now announced a compromise. Glomar Challenger will be retired in about 1983, when experiments would be transferred to Explorer. Plans to equip Explorer with a "riser" — a casing around the drill used to prevent blow-outs from occurring if pockets of oil or gas are hit — would be carried out 2 or 3 years later. After that the Explorer would divide its time between OMDP (to which industry will contribute about \$18 million a year) and an extension of the current non-riser drilling being carried out by Challenger, a solution which seems acceptable to both scientists and **David Dickson** industry representatives.

A Press Council adjudication

This is the text of an adjudication issued by the UK Press Council on 26 August:

The Press Council finds the author was invited to submit an article but not that there was an undertaking that the article would be published. Notwithstanding the invitation, whether it would be published remained a matter for the editor's decision. Alterations which met the criteria laid down by the editor had not been made by the time he told Dr Miller he had decided after all not to publish the article and suggested he send it elsewhere.

The editor did, as Dr Miller complains, submit the article to another scientist mentioned in it, but the Press Council is satisfied he did so with Dr Miller's consent and no complaint can be made at this.

The council is not satisfied the editor used material from the unpublished article in his editorial comment dealing with the same subject. The council, however, believes that the timing of the editorial comment so soon after the rejection of the article was unfortunate. It shares the view put to it by the editor that he ought to have given Dr Miller a fuller answer sooner — and thus an opportunity to submit his article to another scientific journal for consideration before publication of Nature's editorial on the subject. The complaint against Nature is not upheld.

The explanatory statement issued by the UK Press Council is as follows:

Although a scientist was invited to submit a magazine article, the decision whether to publish it was for the editor, the Press Council has ruled.

Soon after an invited article was rejected, the magazine commented editorially on the same subject. Despite the unfortunate timing, the Press Council said, it was not satisfied the editor used material from the submitted article.

The council did not uphold a complaint against *Nature* by Dr Jeffrey H. Miller, professor in the Department of Molecular Biology at the University of Geneva that, having refused to publish an invited article submitted to him in confidence and amended by the author according to requirements stipulated by the editor, the editor submitted the article to a person mentioned in it and used some of the material in the article as the basis of his own editorial comment.

Dr Miller suggested an article to *Nature* and was asked to submit it. In it he forecast growing controversy over mixed industrial and academic research into applied microbiology. The article contained criticisms of Professor Charles Weissmann, of the University of Zurich.

Mr John Maddox, who then became editor of *Nature*, sent Dr Miller an amended copy of the manuscript, saying charges against individual scientists should be justifiable and temperate. Dr Miller sent a second version including

many suggested changes but which was still critical of Professor Weissmann.

The editor phoned Dr Miller saying he was ready to publish the article but would like to show it to Professor Weissmann. Dr Miller gave permission. Mr Maddox later said he could not publish the article: it was too directly concerned with Professor Weissmann's work.

Dr Miller then sent a third version, saying he had agreed to the professor seeing the article because he assumed it was agreed in principle to publish it. Although he asked for an explanation if the article was not published, he did not receive one.

Soon afterwards *Nature* commented editorially on the propriety of academics being involved with commercial interests, saying attempts to exploit new genetic manipulation techniques could sour the atmosphere of academic research.

After the solicitors for Dr Miller complained to the Press Council, the editor said it was a convention of the scientific press that personal criticism by outside contributors was not published without warning. He would have replied to Dr Miller if the latter had not told a colleague that he would complain to the council if his third draft were not published.

Dr Miller said the editor's plagiarism of themes not before similarly expressed made it difficult to publish his article elsewhere. Mr Maddox argued that Dr Miller's comment covered the whole academic community while the leading article dealt primarily with molecular biology.

Mr Maddox said there were incorrect and unpublishable charges against Professor Weissmann in the first version. He had had two long phone conversations with Dr Miller. In the second he said he would publish the article if the professor could see it. Discovering that Professor Weissmann acted with propriety had undermined his confidence in Dr Miller's reporting.

Dr Miller commented he had understood the article was accepted for publication and only the Weissmann references were in doubt. The reasons given for withdrawal had no substance and the editor drew heavily on his article.

Dr Miller could not attend an oral inquiry. Mr Maddox told the complaints committee he showed the second version to Professor Weissmann, who explained he had a formal agreement regulating his commercial activities. This was not mentioned in Dr Miller's drafts. Mr Maddox said that his reaction to the third draft was that Dr Miller could have made the amendments earlier but that on reflection he regretted his rather hottempered reaction that there was no point in further correspondence.

Nature has no further comment to make except to hope that Dr Miller (and Professor Weissmann) will continue to contribute to its columns.

CORRESPONDENCE

Coping with cuts

SIR — The sad plight of UK universities facing increasing costs and diminishing financial support, possibly even the elimination or demotion of "redundant" universities, moves me to suggest an arrangement not uncommon in American universities, whereby members of university faculties have 9-month rather than 12-month appointments.

This means that faculty members have 3 months in the year free for other activities. Scientists and engineers can frequently find summer employment in government and industrial laboratories, where the broader experience may well be beneficial to their university teaching and research. In any case, the experience may be valuable in combating the ivory tower outlook and maintaining contact with the real world. Colleagues in the humanities may find it more difficult to obtain alternative summer employment, but they would be free to write books, paint pictures, compose music and thereby practice the arts they teach.

In many cases, it may not be necessary for the "9-month scientist" to forsake his laboratory. A large part of American (meaning US) university research is funded by grants from government agencies and from industries. It is common practice for a research proposal to include not only support for a post-doc associate or a graduate student assistant, but also an item for 50 per cent or even 100 per cent of the time of a faculty member for two or three months of the year. Such support is by no means automatic but depends on the quality of the proposal, that is, on the quality of the person making the proposal.

Thus in one way or another the really capable people on university staffs can add usefully to their salaries and those who have "retired" from active productive scholarly work and have little or no standing in their subjects are left where they belong, at a lower level on the financial ladder.

Much good can come from the operation of the free enterprise system, and those who prefer the old, easy-going ways must accept lower annual remunerations.

G.W. BRINDLEY

Pennsylvania State University, Pennsylvania, USA

Nuclear electricity

Sir - In commenting on the analysis of relative costs of nuclear and coal-fired electricity given in Appendix 3 of the Central Electricity Generating Board (CEGB) 1979/80 Annual Report, I stated that "the full calculation (of costs corrected for inflation) can only be undertaken when the CEGB decides that its present policy of withholding the data . . . is counterproductive" (Nature 287, 674; 23 October 1980). I had first asked in specific detail for the data at the beginning of September 1980 and had pursued the matter through both the Department of Energy and the CEGB to the extent of getting a discussion meeting with both department and board officials present. In spite of this the detailed figures of capital cost only became available at the end of March 1981 and then only as the result of a parliamentary question put down on 2 February.

The results of the present calculations, utilizing the newly available data are summarized in the table below. These calculations are significantly different in method from those used in an earlier paper (Energy Policy, December 1980, p.344-6) and referred to in my letter of 23 October. The retail price index (RPI) has been used to correct for inflation and a uniform interest rate of 5 per cent has been applied instead of the historic National Loans Fund rate.

However, as the table below shows, even with these modifications the inflation corrected cost of nuclear electricity from Magnox stations is still 18 per cent above that of comparable coal fired stations, instead of 17 per cent below as given by historic costs, and if a previously unconsidered effect of inflation on nuclear fuel costs is included, the margin becomes 34 per cent above that for coal.

Calculations similar to those for the stations of Table 1, Appendix 3 have been done for Hinkley Point B and Drax (first half) (Table 2). The results are also given below. The full paper giving the details of the calculations and dealing also with stations under construction and future stations (Tables 3 & 4, Appendix 3) is in preparation (to be submitted to *Energy Policy*).

Generation costs at nuclear and conventional stations (pence per kWh 1979/80 prices)

Stations commissioned between 1965 and 1979

	1	2	3
Nuclear	1.30	2.06	2.34
Coal-fired	1.56	1.75	1.75
Nuclear/Coal %	83	118	134

Hinkley Pt B (AGR) and Drax (first half) (coal-fired)

	4	5	6	7
Hinkley Pt B (nuclear)	1.35	1.80	2.06	2.38
Drax (first half) (coal-fired)	1.52	1.69	1.69	1.69
Nuclear/Coal %	89	107	122	141

Notes to columns: (1) Historic costs as given by CEGB in Table 1, Appendix 3, 1979/80 Annual Report. (2) RPI corrected capital costs, 5 per cent interest rate and fixed costs corrected for load factor equal to availability. (3) As 2, but with the addition of an estimated minimum inflation correction for nuclear fuel costs. (4) Historic costs as given by CEGB in Table 2, Appendix 3, 1979/80 Annual Report. (5) RPI corrected capital costs and 5 per cent interest rate. (6) As 5, but with the addition of an estimated minimum inflation correction for nuclear fuel costs. (7) As 6, but estimated probable fuel cost correction.

Finally may I take up one point in Dr Jones's letter (Nature 288, 638; 1980) in which he criticizes my use of the combined coal and oil fuel costs in Fig. 1 of my letter of 23 October. Separate coal fuel costs in p/kWh similar to the combined ones of Table 9 of the CEGB Statistical Yearbook are not available, but figures of coal prices to the CEGB in p/GJ from 1960/61 to 1979/80 have been supplied by the Commercial Controller. When the real price index is normalized to equality with the coal and oil figures for 1972/73 and plotted on the same graph there is no significant difference between the points. I understand from Dr Jones that he was considering National Coal Board production cost data which may well give a different picture, but it is the price to CEGB and specifically the coal fuel cost in p/kWh which I was dealing with and my graph is an accurate reflection of this.

J.W. JEFFERY

Birkbeck College, Malet Street, London WC1, UK

Attack on Tamuz

SIR — Your recent editorial "Making Israel atone for Tamuz" (Nature 18 June, p.523) leaves out many facts which are important in considering the reasons for Israel's attack and the reality of the situation.

As you and I are aware, nations do what is in their best interest regardless of what treaties they do or do not sign. Just because one nation is a signatory of the Non-Proliferation Treaty does not mean that it will not produce a nuclear weapon. Iraq has been one of Israel's most aggressive and belligerent neighbours, and in fact these two countries are still at war with one another, as no peace treaty has ever been signed. What could this or any other country do if indeed Iraq or any other nation had a nuclear weapon and threatened to use it against an enemy? We could not stop the Soviet Union from invading Afghanistan, nor prevent the problems of Iran. We cannot even clear up the fighting in Lebanon. The world needs Iraq's oil, so "international pressure" would never work

I agree with your statement concerning the use of oil to generate hydroelectric power, but why did Iraq refuse to accept lower grade uranium that would work very well in a nuclear reactor to produce electricity, but would not be able to produce atomic weapons? Iraq demanded from France weapons grade uranium or their oil supply treaty would be null and void. In addition, one of the inspectors from the International Atomic Energy Agency stated during an interview that the reactor at Tamuz could easily have produced nuclear weapons and that such production could have been shielded from any inspector, thus making the whole question of on-site inspection ludicrous. Although Iraq was supposed to return the spent uranium to France for reprocessing, Iraq also had uranium already purchased from Third World nations, thereby bypassing France completely. You also do not mention that Iraq had contracted with Italy to build a "hot cell" plant that would also allow for enriching and processing plutonium for no other purpose than to build an atomic bomb. M.S. PASCAL

Englewood, New Jersey, USA

SIR — Israel's attack on the Iraqi reactor may have been politically unwise, even immoral (although I suspect Benthamites might be able to generate some fairly strong Utilitarian arguments in support of the raid). It is, however, something approaching hyperbole to characterize the raid as a flagrant violation of international law (Nature 18 June, p. 523), as Iraq remains in a technical state of war with Israel, and has repeatedly called for the destruction of the "Zionist entity".

It is also somewhat naive, to be gentle, to assert that Iraq's acceptance of the principles of the Non-Proliferation Treaty assures compliance with its provisions. Soviet citizens who seek the enforcement of the principles of the Helsinki accord often must pack for very cold climates on very short notice.

On judgement day when we must all atone, there may be many whose need for absolution will be greater than that of the Israelis.

New York, USA

ELLIOTT B. GROSSBARD

Neutron bombs

SiR — Neutron weapons, I was astounded to read in your journal, "are a blessing and not a curse". With blessings like that, who needs curses?

That surely is the point about the theory of nuclear deterrence. Its insane logic presents every new cursed twist of the nuclear arms race as a blessing. The 50 and 100 megaton weapons were supposed to be a blessing because politicians would hesitate more before unleashing Armageddon. You now argue that neutron bombs are a blessing because they obviate the need to use the big bombs first. Next you will argue, if a low-radiation highblast bomb is developed, that this is also a blessing since it will destroy property but not people. And a Doomsday bomb that would blow the world asunder would also be a blessing because of the fear of starting a war that it would put in the enemy.

In the last analysis, those who support the nuclear deterrent theory will admit that these weapons are all a curse. That's why one wants nuclear disarmament. But that sane admission cannot co-exist with the dogma that new weapons of death are a blessing. If you allow it to, you become guilty of a form of double-think which is scientifically dishonest and politically and militarily disastrous.

As for the "cynical" (as you call it) argument that neutron weapons will help disarmament negotiations, it is not so much unrealistic, as you argue, as just plain stupid. It is surely obvious that balanced mutual force reductions are more difficult to obtain agreement over the more numerous become the weapons systems deployed on both sides. To argue the opposite is perverse.

I am a "lay" reader of *Nature*. Your support of neutron weapons seems to me to be a betrayal of the efforts of your contributors to understand — and improve — the world we live in. Your arguments do disservice to the entire scientific community and the human values that give it purpose.

MARTIN RABSTEIN

London N5, UK

THE phrase complained of appears in the following sentence: "In the bizarre logic of the nuclear battlefield, in which strategic nuclear weapons are intended to stay forever in wonderland, neutron weapons are a blessing and not a curse." — Editor, Nature.

Shielding tanks

SIR — The United States Government and the British Ministry of Defence claim that the neutron bomb is a weapon developed for use against tanks. You have stated (Nature 13 August, p.571) that these weapons are more easily (than "ordinary" nuclear weapons) directed against military personnel.

By making reasonable assumptions about neutron weapons concerning the neutron energy spectrum and the ratio of the neutron and gamma energy fluxes it can be shown that a radiation shield could be incorporated into the armour of a tank which would reduce the radiation dose to the crew by a factor of over 100. Such a shield would negate the enhanced radiation properties of a neutron weapon. The neutron bomb would become no more effective than normal nuclear weapons of similar explosive power.

The precise constituents of such a shield would depend on whether it would be attached on the outside of the tank or added as a lining to the crew compartment. Let us assume that for the tank armour possibly 5 cm of steel can be used as the outer component of the shield. A lining of 10 cm of polythene or other hydrogenous material would thermalize the neutrons and a millimetre of boron or other neutron absorber would remove the neutrons. The inside layer would be a gamma shield and 1 cm of lead would be adequate. Such a shield would add about 5 tons to the weight of a 30 ton tank.

This type of shield, which could be widely incorporated into tanks and military vehicles, would make neutron bombs no more effective against tanks than the small fission nuclear weapons which are reputed to be widely distributed to United States forces throughout the world.

The United States insistence that neutron bombs are for use against tanks in the face of widely available information which enables tanks to be protected against the special effects of neutron bombs, forces the impartial observer to attribute the real reason for the production of neutron bombs to their potent ability to kill people whilst causing only the minimum of collateral damage.

J.E.F. BARUCH:

The University, Leeds, UK

Local reaction

SiR — Apparently, Lord Rutherford's maxim that there is mathematics and physics and that all other activities are stamp collecting, is still valid in Ms Rich's writings on Yugoslav scientific institutes. The result is a biased assessment of the scope of their competence, specifically in problems related to nuclear power (Nature 11 June, p.446-447). A quick check with the Science Citation Index would show the scientific activities of the two cited "physics" institutes to cover a broad range in Rutherford's "philatelistic" category.

Contrary to the statements in *Nature*'s article, there is no "local misunderstanding of the distinction between the charging of a reactor and its start-up". There is no misunderstanding or lack of knowledge with respect to reactor or nuclear fuel technology, much less on the importance of additional power sources in a power-hungry country with few significant energy resources still available for exploitation. Nor has there ever been any misunderstanding based on ideological doctrinarism, contrary to what could have been perceived from another article by the same author (*Nature* 288, 5; 1980).

The dispute is over the technological and organizational discipline necessary in building, starting and operating high technology units like nuclear reactors. The one mishap, in 1958, was the result of just such a typical breach of work discipline.

The dispute is rather between the narrow, mission-oriented technocrats and the concerned scientists on the consequences of siting large facilities in an already ecologically strained region. Scientists insist on careful planning and broadly based environmental impact assessment. Their concern reaches beyond the narrow, albeit possibly correct, advice of "no technological obstacles", offered by a reputable international expert to our supposedly less developed country. The dispute is well within the framework of questions raised in reviewing the Final Safety Analysis Report, and concerns another problem — that of the reference plant for the

Krško unit.

The scientific community is not beyond reproach either. Its lack of credibility, or "weight", with the decision-making social strata stems from some recent and not so recent failings. But it should not be blamed for either disciplinary monoculture or primitive ecological extremism.

I could not refrain from voicing my displeasure with these articles, although this letter might prove just another exercise in futility. Ms Rich's articles remind me of a statement made by one of your great historians. Writing about an infamous propaganda minister of recent European vintage, he claimed that the points in the minister's propaganda items were made so well, that even the opposite of it was still not the truth.

VELIMIR PRAVDIĆ

Ruder Bošković Institute, Zagreb, Yugoslavia

VERA RICH WRITES — I cannot accept Dr Pravdic's statement that there is no "local misunderstanding". During my visit to Zagreb in March and April of this year, I spoke with a number of members of the public who interpreted the announcement of the imminent "charging" of the reactor to mean that it would "start working" immediately. I fully agree that the main dispute lies between the "concerned scientists" and the technocrats. Perhaps the undoubted local apprehension arises from a fear that in such a conflict, the technocrats may win.

Mystery genre

SIR — In reading Edmund Leach's review of the book Genes, Mind and Culture by C.J. Lumsden and E.O. Wilson (Nature May 21, p.276) it strikes me that comments such as "crass idiocy", "parody of science", "gibberish" and "phoney" might be a trifle intemperate coming from a reviewer who admits that he cannot comment on the bulk of the work, which is in neuroscience and psychology.

What is far more intriguing is the question of what Leach could have had in mind when he referred to the "genre" to which Genes, Mind and Culture belongs. At first it went right by me, but I did a double take later when I recalled that Leach had once written a review on the genre of "popular ethology" books, such as those of Lorenz and Ardrey. It was hilariously entitled "Don't say 'Boo' to a Goose" and appeared in the New York Review of Books.

That was 15 years ago. Is it possible that Leach is still referring to the same genre? I ask, because — significantly — he does not mention the major theoretical work Sociobiology in his list of E.O. Wilson's credentials. Worse, he calls Wilson a "popularizer". Surely there is not a regular reader of Nature anywhere — on either side of the well-known floor — who conjures up the image of "popularizer" when Wilson comes to mind.

I urge that Leach be invited to identify the mysterious genre in which he has classified the Lumsden-Wilson book and if it is ethology—there is virtually no ethology in Genes, Mind and Culture—then clearly his review must be rescinded from the pages of Nature as having been written by a uniquely unqualified party.

Nobel Physics Prize in perspective

Robert Marc Friedman*

WITH the time for the announcement of the 1981 Nobel Prizes approaching, it is timely to consider the nature of these awards. There is a need for a wider understanding of the process by which these honours are determined: a realistic appreciation of the prizes can serve only to enhance their value¹. So far, however, little has been written about the decision making process. By drawing on historical research, I shall seek to elucidate some of the issues which have been raised, especially relating to the scope of the prize in physics.

To what extent does Nobel's will define the field of physics that can be considered for a prize? Little was specified in Nobel's will and, while drawing up the statutes, the prize-awarding institutions resisted all attempts to delineate or define the broad terms "physics", "chemistry" and "physiology and medicine" used in the will². Hence, when the members of the committee for the prize in physics met for the first time in 1901, they were faced with

B. Hasselberg, wrote that the prize could be awarded for great achievements not only in "pure Physics properly so-called", but also in "the sciences most closely connected with Physics and for the cultivation of which physical methods are employed[;] as [such] Astrophysics and physical chemistry are also to be taken in account. This I suppose will certainly answer to the proper meaning of the testator. Whereas thus ... pure Astronomy or celestial dynamics or Astrometric [sic] will scarcely be included, any work on Astrophysics of great importance deserves certainly a thorough consideration"5.

Moreover, the inclusion of meteorology raised little, if any, objection; as well as acting as host for this meeting, the Meteorological Institute's director, Professor H. H. Hildebrandsson, served on the original committee. At the meeting, committee members called for strengthening the expertise in "cosmical physics" (meaning

The history of the award of the Nobel Prize in Physics, which is partly the history of interpreting the statutes, also depends on the development of physics in Sweden. The now traditional restricted scope of the prize has its origin in past controversies, not formal rules. Einstein's relativity and Bjerknes's meteorology were both casualties.

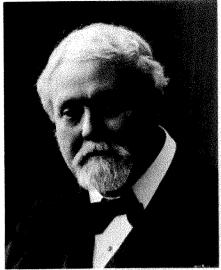

the same ambiguities in the statutes that we recognize today. How ought they interpret and reconcile such clauses as "have conferred the greatest benefit on mankind" and "most important discovery and invention within the field of physics"? The provision in the will that works "during the previous year" should be interpreted to mean "for the most recent achievements . . . and for older works if their significance has not become apparent until recently", created further opportunity for uncertainty and arbitrariness.

During the early years, both the committee and the executors of the estate understood that physics ought to be defined as broadly as possible³. At the first committee meeting, held at the Meteorological Institute of the University of Uppsala, the committee agreed that astrophysics was eligible while astronomy was not⁴. More specifically, in responding to an inquiry, the head of the committee,

the physics of the macro-world) on the grounds that nominations from this branch of physics would surely increase⁶. In fact, during the next thirty years, nominations to honour various astrophysicists, geophysicists and meteorologists were not and could not have been formally disqualified for being outside "physics" (for example, G. E. Hale, H. Deslandres, K. Birkeland, C. Størmer, N. Shaw, J. Hann, V. Bjerknes). In short, neither Nobel's will nor the statutes restricted the definition of physics to a narrowly defined group of specialties.

Narrow scope

I shall argue that the subsequent restriction of the scope of the physics prize stemmed from a determined effort within the Swedish physics discipline. Not surprisingly, Nobel Prize deliberations became enmeshed in the process by which various factions within the Swedish physical science community attempted to define and to legitimize their particular notions of physics: its objects, methods and goals. The history of prize decisions, being also the history of interpreting the

H. H. Hildebrandsson, professor of meteorology and member of the committee for physics (1901–1910), hosted the committee's first meeting.

statutes, cannot be divorced from the development of the physics discipline in Sweden. Consequently, various traditions have been established for interpreting the statutes, which arose from past conflicts, debates and strategies for attaining authority, that have little relevance for the present. Traditions grounded in past contingencies ought not be mistaken for immutable, formal rules and regulations. Unfortunately, literature concerning the Nobel Prizes tends to discuss the awards in the passive voice, and thereby tends to reinforce the mystique of anonymity and objectivity in the decision process. This frequent use of the passive voice also slights the committee members, the difficulty of whose task is easily overlooked.

The Nobel Committee

Committee members play critical roles by evaluating nominees and selecting nominators. During the period for which committee archives are accessible (1901-30), the committee's five members judged annually the nominations received and then proposed to the physics section (Klass) of the Royal Swedish Academy of Sciences how the prize should be allocated. Following approval from the Klass, or suggestion of an alternative proposal, the full Academy then voted on the award. On some occasions, the Klass, and even the Academy, disagreed strongly with the original choice, so that the committee had to justify its actions carefully, especially when these were controversial or not unanimous. The committee members also drew up each year a list of institutions and individuals who would be invited to send nominations for the following year. Thus the committee regulated to some extent the nominators who might supplement the fixed group entitled to make nominations - members of the Academy, former prize winners, and professors of physics at Scandinavian universities and technical colleges.

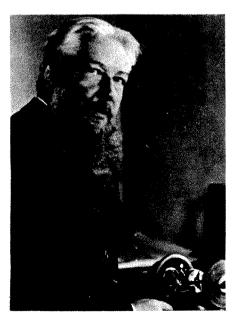

^{*}Institute for Studies in Research and Higher Education, Norwegian Research Council for Science and the Humanities, Wergelandsveien 15, Oslo 1, Norway.

Dissent over Einstein

The influence of the Swedish physics discipline on Nobel Prize decisions is well illustrated by Albert Einstein's prize. In 1922 the Academy voted to award Albert Einstein the previously "reserved" 1921 Nobel Prize "for his services to theoretical physics, and especially for his discovery of the law of the photoelectric effect". Both the timing and the citation have long raised questions among Nobel Prize watchers. If the opinions of the scientific community at large, or more specifically of the nominators, had been decisive, Einstein would certainly have received a prize earlier, and for his theories on special and general relativity.

As early as 1910, W. Ostwald began nominating Einstein for his work in special relativity. During the First World War and immediately thereafter, many nominations for Einstein arrived specifying his research on relativity, brownian motion and specific heats of solids and/or quantum theory in general. Following the famous 1919 solar eclipse experiment which, according to many, confirmed Einstein's prediction of the bending of light by the gravitation of a massive body, a virtual flood of nominations for Einstein ensued.

Yet, in 1920, the committee and the Academy agreed to award the prize to Charles Guillaume. One year later, claiming that they could not find any grounds for awarding a prize to Einstein, the committee, followed by the Academy, voted to reserve the 1921 prize⁷. Finally, in 1922 Einstein received a prize, specifically for the law of the photoelectric effect—not for his quantum theory to explain the law, nor for relativity in any form. Of the approximately fifty nominations of

W. Ostwald nominated Einstein for the 1910 physics prize, specifying work on "the relativity principle". By 1922 many physicists had proposed awarding a Nobel Prize for Einstein's relativity theories; these included: Bohr, Eddington, Haas, v. Laue, Lorentz, Planck, Sommerfeld and Zeeman.

EINSTEIN'S RELATIVITY THEORY OF GRAVITATION

The debate on Einstein's theory was in full flow in *Nature* of 4 December 1919. E. Cunningham wrote:

THE results of the Solar Eclipse Expeditions announced at the joint meeting of the Royal Society and Royal Astronomical Society on November 6 brought for the first time to the notice of the general public the consummation of Einstein's new theory of gravitation. The theory was already in being before the war; it is one of the few pieces of pure scientific knowledge which have not been set aside in the emergency; preparations for this expedition were in progress before the war had ceased.

The question from which Einstein began the great advance now consummated in success was this. If energy and intertia are inseparable, may not gravititation, too, be rooted in energy? If the enrgy in a beam of light has momentum, may it not also have weight?

The mere thought was revolutionary, crude though it be. He asked for an out-and-out relativity of space and time. He would have it that there is not ultimate criterion of the equality of space intervals or time intervals, save complete coincidence. All that is asked is

that the order in which an observer perceives occurrences to happen and objects to be arranged shall not be disturbed.

This, then, was the mathematical problem. The pure mathematics required was already in existence. An absolute differential calculus, the theory of differential invariants, was already known. In pages of pure mathematics that the majority must always take as read, Riemann, Christoffel, Ricci, and Levi-Civita supplied him with the necessary machinery. It remained out of their equations and expressions to select some which had the nearest kinship to those of mathematical physics and to see what could be done with them.

Although in the letter immediately before Cunningham's report, Alexander Anderson of University College Galway concluded:

I THINK it is quite likely that if the refraction of the atmosphere of the Earth due to density changes during an eclipse could be accurately obtained and allowed for, it would be found that there is no Einstein effect at all.

Einstein over the years, the law of the photoelectric effect was specified by only one nominator. Certainly, a familiarity with the committee must be sought to begin understanding these events.

Experimental bias

At the time, three of the committee's five members belonged to the Uppsala tradition of experimental physics — B. Hasselberg, G. Granqvist, and A. Gullstrand. The others were S. Arrhenius (physical chemistry) and V. Carlheim-Gyllensköld (mathematical and cosmical physics). The committee's strong experimentalist bias proved significant from the start in determining Nobel Prize decisions and for interpreting the statutes.

Debates on the role of mathematics and theory in physics that had begun in the 1890s carried over into deliberations on the prize. Hence, even in the case of a worldwide campaign for Henri Poincaré, in which his mathematical physics qua physics was delineated from his purely mathematical accomplishments, the committee did not see fit to recommend him for the prize8. In a protest note, Carlheim-Gyllensköld pointed out the committee's general unwillingness and inability during the first ten years to evaluate nominations in mathematical physics such as those of Boltzmann, Heaviside, Kelvin and Poynting9. Arrhenius had commented that Uppsala physicists consider "spectral analysis . . . the only part of physics worth pursuing '10. Indeed, Hasselberg did "all in my power to procure the prize" (1907) for A. A. Michelson, who had recieved but two nominations, not for his role in the aether-drift experiment but, rather, primarily for his work in precision spectroscopy and metrology11. Hasselberg admitted that he found a "sympathy for an

area closely connected with my own speciality...I cannot but prefer works of high precision"¹².

Other examples abound. Thus the proposal for the 1908 prize was sabotaged partly by those who believed it "unjust" to award a prize to a theoretician, M. Planck, without dividing the honour with an experimentalist¹³. Apparently, to ensure the defeat of the Planck nomination, the Academy was informed of Planck's questionable "hypothetical molecules of energy", which were not mentioned in the committee's report14. Not surprisingly, the majority's stringent demands that theory be completely verified by experience virtually precluded a prize for Einstein's various theoretical endeavours. Yet, did the 1919 eclipse experiment have any impact on the committee's evaluation?

Although often hailed as a "crucial

B. Hasselberg. "Icannot but prefer works of high precision" — on A.A. Michelson's spectroscopic measurements. "It is highly improbable that Nobel considered speculations such as these to be an object for his prizes" — on Einstein's relativity theories.

experiment" that proved Einstein's general relativity, the 1919 test left many reasonable physicists unconvinced, among them the members of the Nobel committee for physics. In 1920 Arrhenius prepared a special report on the subject for the committee in which he noted that objections could be made against the accuracy of the observations, which were therefore not a proof of the prediction¹⁵. In any case the prize for 1920 seemed already determined. Hasselberg then lay gravely ill. Having championed precision measurement, especially in spectroscopy, Hasselberg now favoured his colleague on the International Bureau of Weights and Measures, Guillaume, whose work in metallurgy was of importance for metrology. To express appreciation for Hasselberg's work on the committee since 1901, the Academy could pay homage to him in this manner.

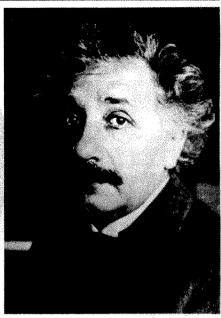

Nevertheless, the Einstein campaign continued to grow in 1921, with strong support for the relativity theories. To ensure a sound evaluation, the committee assigned the task of writing a special report focusing on Einstein's relativity and gravitational theories to its esteemed member Gullstrand, who would have received the 1911 prize in physics for his contributions to dioptrics had he not first been named for a prize in medicine¹⁶. In his fifty-page report, Gullstrand concluded that neither the general nor the special theory of relativity warranted a Nobel Prize¹⁷. In 1922 he brought his report up to date and came to the same conclusion. Acceptance of these theories remained simply "a matter of faith (trossak)"18. He resolved that Einstein must never receive a prize19.

The 1922 Prize

In general the committee supported Gullstrand. Hasselberg asserted from his sickbed that "it is highly improbable that Nobel considered speculations such as these to be an object for his prizes"20. Nor was there much sympathy for honouring Einstein's other theoretical contributions. Even his theory of the photoelectric effect was not considered significant enough to warrant a prize, since much of the elaboration of the quantum theory entailed others' endeavours²¹. Yet, when the Klass met to vote on the committee's proposal to reserve the prize, mathematical physicist C. W. Oseen suggested that Einstein's law, rather than the theory, ought be considered for a prize since this law forms the foundation for all the recent remarkable achievements in atomic physics²². The Klass then voted to acknowledge the significance of Einstein's discovery of the law of the photoelectric effect, but resolved that it was not worthy of a prize²².

Oseen did not intend to let the issue end there. He was concerned not so much with Einstein but with Niels Bohr, who had been repeatedly nominated since 1917²³. He regarded Bohr's atomic model as "the

A. Gullstrand (left) prepared special reports on Einsten's relativity and gravitational theories in which he concluded that they did not warrent a Nobel Prize. The acceptance of these theories remained, even after 1919, "a matter of faith (trossak)".

most beautiful of all the beautiful' in theoretical physics, and was thus determined that this work should receive a prize²⁴. Moreover, he had already begun on a campaign to strengthen Swedish physics, especially by introducing theoretical physics. For Oseen, atomic physics offered the challenge of theoretical investigation while remaining tightly disciplined by experiment. Previously, the experimentalists on the committee balked at approving Bohr's atom model which, they claimed, stood "in conflict with physical laws" and hence reality²⁵.

Now, in 1922 Oseen proposed Einstein for the discovery of the law, and then joined the committee as a special extra member. Oseen wrote special reports on Einstein's law and on Bohr's atomic theories. He carefully argued that experimental investigations had confirmed Einstein's law so thoroughly that it must be considered among the "soundest propositions physics now possesses"26. Hence Bohr's models, which he argued were built on this law, must be regarded as being in solid agreement with physical reality²⁶. Finally, not without some difficulty, Oseen prevailed. Although further study is needed, this episode demonstrates the importance of the committee membership's interests and philosophies of science for Nobel Prize decisions.

The Einstein deliberation came at a turning point in the development of Swedish physics and of the committee. By 1923, after the deaths of Hasselberg and Granqvist, Oseen was elected to the committee as a regular member and was ioined by his Uppsala colleague, atomic physicist Manne Siegbahn. Together with Oseen's friend, Gullstrand, the three Uppsala physicists commanded a majority on the committee and could plan and act together on Nobel Prize matters. Oseen's broad knowledge, international reputation

and aggressive determination allowed him to assume leadership in the committee. His vision called for an overhaul of Swedish physics: stronger links with major foreign research centres, and greater visibility and prestige to ensure adequate research funds and university positions²⁷. By promoting atomic physics, in which experiment and theory intimately progress together, he hoped to overcome traditional prejudices and to institutionalize a theoretical physics standing apart from abstract mathematical physics and mechanics. Yet, to be successful in this "new epoque"28, which he declared after the election of Siegbahn to the committee, they not only had to promote and to legitimize their preferred research programmes, but would also have to eliminate what they considered insignificant specialities. Starting in the 1920s, the Uppsala group began a determined campaign to restrict the definition of physics within the Academy and with regard to the Nobel Prize. To pursue this strategy they could try to change the statutes formally, control membership in the Klass and committee and/or establish traditions for interpreting the statutes by honouring particular specialities and blocking others.

Arrhenius and astrophysics

Change of statutes entails considerable debate and great difficulty, since the entire Academy must vote on such motions. Thus the committee members tried to avoid formal motions to change the statutes since these inevitably breed conflict within the committee and the Klass, which in turn weakens their posture in the Academy. This became clear when, in 1923, the new Uppsala group and Arrhenius attempted to eliminate astrophysics from the scope of the prize in physics. Arrhenius, who wrote the proposal, seems to have feared that the establishment of new Nobel institutions

S. Arrhenius, member of the committee for physics, had originally supported cosmical physics, but in 1923 he tried unsuccessfully to eliminate formally astrophysics from the scope of the Nobel Prize for physics.

would threaten his own Nobel Institute for Physical Chemistry. (According to the statutes, Nobel funds can be used to establish research institutes where nominations can be evaluated.) Previously, only Arrhenius's institute had been supported in this way, but during the war Carlheim-Gyllensköld, suggested a department for cosmical physics that was later followed by detailed plans for an astrophysics centre^{29,30}.

Consequently, Arrhenius proposed that astrophysics no longer should be considered part of physics. Although previously a strong supporter of cosmical physics, he now argued that astrophysics had progressed so dramatically, that it now incorporated all physical astronomy31. Thus, he concluded, astrophysics is astronomy, and therefore not part of physics. Carlheim-Gyllensköld vigorously opposed this action and, predictably, the statute change was defeated³². A much easier strategy entails dismissing outright nominations in cosmical physics as "not being significant for physics", the phrase commonly used by writers of the general report to the Academy. Hence, Hale and Deslandres, previously considered certain winners of the prize, could now be quickly dismissed once Hasselberg had died and Arrhenius no longer supported these sciences.

To proceed in this way requires a committee and a Klass that does not object too strongly—so that membership must be controlled when possible. When the physics section of the Academy expanded from 6 to 10 members in 1904, it was given the title "Physics and Meteorology". Having established strong research traditions in meteorology during the nineteenth century, Swedish meteorologists received a number of places in the Klass. By 1919, however, the promise of Swedish meteorology had waned and a

long, bitter and inconclusive feud concerning atmospheric thermodynamics raised doubts over the personal and/or scientific reliability of some of the meteorologists. Oseen was prompted to express concern whether any branch of "terrestrial physics" could become rigorous, given the scale of geophysical phenomena and lack of laboratory testing possibilities³³; he sensed a "relativity of all knowledge" within these sciences33. Uppsala experimental physicists shared this belief. They attempted to reduce the meteorological influence in the Klass and prevent the awarding of a Nobel Prize to this science, as this would legitimize meteorology as part of physics in the Academy.

Meteorology out of favour

The campaign against meteorology in the Klass seems to have begun after the death of foreign member J. Hann, an Austrian meteorologist. The election of foreign members has a double significance. On occasion, such an election is a stepping stone for prospective Nobel Prize candidates; in general, all foreign members have the right to propose candidates for the prize. In this instance, members of the committee tried to obtain before the meeting the signatures of a majority of the Klass for the appointment of a physicist, thereby precluding replacing Hann with another meteorologist34. Arrhenius sketched a nomination for Planck and travelled up to Uppsala; however, rather than speaking with meteorologist Hildebrandsson as promised, he carefully avoided him while meeting the other physicists. The elderly Hildebrandsson felt betrayed³⁵. But his subsequent request at the meeting of the Klass that they promise to elect a meteorologist next time, was defeated36. And, when foreign member Röntgen died the following year, Gullstrand organized a comparable campaign against electing a meteorologist, saying he would refuse to vote if a meteorologist were proposed³⁷.

Similarly, when Klass members Hasselberg, Granqvist, and Bäcklund died, they were rapidly replaced by physicists Siegbahn, Pleijel, and Oseen. After the death of meteorologist N. Ekholm in 1923, Hildebrandsson feared the worst and decided to take the offensive by bringing the touchy issue into the open and up to the entire Academy. Now that physicists had twice been elected to succeed meteorologists, "should this happen yet again, then it must be regarded as a wish of the physicists to get rid of meteorology within the Third Klass"38. He pleaded that a meteorologist should now be elected because, out of the ten members of the Klass, the two remaining meteorologists were so old that there was a real danger that meteorology would soon lose its representation in the Academy. To refuse Hildebrandsson would have been a personal insult, so that his candidate, A. Wallén, was elected³⁹. Nevertheless, when

the other meteorologist, Hamberg, died shortly afterwards, Gullstrand warned members of the committee that "under all circumstances we must act [ställa oss], so that we do not get in yet another weak meteorologist".

This time they acted quickly. Led by committee members Oseen, Siegbahn, Gullstrand and Arrhenius, a majority signed a proposal for physicist C. Benedicks. Carlheim-Gyllensköld, a cosmical physicist, opposed these efforts. When he next came up for re-election on the Nobel committee, Oseen, Gullstrand, and Siegbahn tried to remove him. First, they tried to reduce the number of committee members from five to four, thereby eliminating his position. When this tactic failed, they used their right to elect a foreign member - and proposed Niels Bohr. Both committee and Klass approved the Oseen-Siegbahn nomination, but the Academy again sensed an Uppsala grab for control, and voted to retain Carlheim-Gyllensköld41.

Similar tactics were used within the committee to avoid awarding Nobel Prizes for meteorological research. Occasional nominations for a meterologist were dismissed as "not significant", or "not confirmed by experience"; but, one nominee reappeared repeatedly, with increasing support from both physicists and meteorologists. Oseen and his Uppsala colleagues were determined that he — Vilhelm Bjerknes — should not receive a prize.

The Bjerknes group

Between 1918 and 1924 a group of Norwegian and Swedish scientists working in Bergen (Norway) under the leadership of Bjerknes transformed theoretical and practical meteorology. Their various conceptual achievements included a new model of the extratropical cyclone, the type of low-pressure system common in the mid-latitudes. Claiming that these atmospheric disturbances are composed of three-dimensional surfaces of discontinuity - fronts - they began conceiving of a cyclone as a wave that forms and evolves along pre-existing polar fronts separating polar and tropical air masses. Their theory provided the first clear physical model of cyclonic evolution, which in turn provided for direct interaction between theory and practice.

The Bergen meteorologists constructed their models over a period of time partly as a result of changes in forecasting methods and partly in conjunction with their efforts to forge new forecasting techniques to meet challenges arising from agriculture, aviation and fishery. Earlier, Bjerknes had for almost two decades worked on an ambitious project to "transform the inexact science of meteorology into an exact physics of the atmosphere". As such, theoretical and physical reasoning informed both the forecasting effort and the new concepts⁴². Having been a

professor of Stockholms högskola from 1894 to 1907, Bjerknes had various supporters — and opponents — within the Swedish scientific community. In particular, the national rivalry that occurs when Norway outshines her traditionally richer and culturally superior neighbour provoked a general reaction of "humbug" from some Swedish scientists⁴³, making it easier for Oseen and others to block Bjerknes's candidature in 1923, 1924, 1926, 1929 and repeatedly in the 1930s.

During the 1920s, several reasons were given for excluding Bjerknes. In brief, the general reports by the committee claimed that the various "empirical" discoveries and improvements in forecasting had arisen simply as a consequence of an improved network of observation stations44. Moreover, Bjerknes's baroclinic circulation theorems for fluids in which density is a function of both pressure and temperature (1898, 1903), should not be considered a discovery or invention; according to Oseen, these innovations and their application to atmospheric and oceanic phenomena were already implied in Helmholtz's earlier circulation theorem for ideal fluids45. Moreover, Oseen and Gullstrand repeatedly asserted that the wave-theory of

C. W. Oseen. His goal of promoting theoretical physics and of improving the international stature of Swedish physics motivated him to attempt restricting the definition of physics within the Academy and for the Nobel Prize.

cyclones and the polar front theory are not proven by experience⁴⁶. Lastly, they held that the Bergen meteorology had been accepted only by a limited number of scientists⁴⁷. How valid were these objections to the Bjerknes nominations?

First, the claim that the Bergen models and improved forecasting arose simply because of the refinement of the observation network cannot be substantiated. Comparable networks had been introduced during the war without similar fruitful results; moreover the Bergen successes did not all immediately ensue. More telling in intent is Oseen's claim that Bjerknes's discovery of the baroclinic circulation theorems did not qualify as a discovery in the sense that Nobel had specified. Yet, as a hydrodynamicist, Oseen knew full well that Helmholtz had never considered the possibility of

baroclinic fluids; indeed, several years earlier, he had declared that Helmholtz received too much credit in this area48. When L. Silberstein derived these theorems independently of Bjerknes, he dismissed such fluids as pure theoretical constructs. Bjerknes's achievement was that he recognized their profound implications for the study of atmospheric and oceanic motions. Revealingly, shortly after Oseen and Gullstrand argued that Bjerknes's work cannot be considered a discovery or invention, they urged the Klass to recall that Nobel's meaning of "discovery and invention" must be interpreted as broadly as possible⁴⁹; on that occasion they were defending a candidate for the 1924 prize against objections of the sort they had levelled against Bjerknes, the nominee here being their colleague, Manne Siegbahn.

Uppsala and geophysics

The cavalier manner in which Bjerknes's work was dismissed was apparent to those who were close at hand. Otto Pettersson, who had sat on the Nobel committee for chemistry and who believed that Bjerknes deserved a prize, recognized the pattern and noted in dismay that apparently, "Uppsala doesn't consider geophysics to be physics" 50. He also wondered whether the committee was competent to appreciate Bjerknes's work or whether Oseen and Gullstrand would ever bother to read enough of it to be able to judge it fairly 51.

Oseen provided other reasons to confirm Pettersson's fear that scientists with great authority all to often misuse their power⁵². After Hildebrandsson's death in 1925, Oseen found an opportunity to use meteorologists against Bjerknes. For the election to the Klass he and other Uppsala scientists backed F. Akerblom, an opponent of the Bergen school and of Bjerknes personally. But when a letter from Bjerknes was distributed suggesting that some of Akerblom's research results seemed to have been borrowed from others, Åkerblom was dropped, leaving as potential candidates two former Bjerknes assistants, V. W. Ekman and J. W. Sandström⁵³. When Sandström was eventually nominated, Oseen almost exploded with rage claiming he would show that Sandström did not even understand the basic physics behind meteorology and oceanography⁵³. He demanded and received a postponenment of several weeks. But instead of demolishing Sandström's candidature, Oseen and Siegbahn had the original proposal replaced by one of their own. Apparently Oseen had learned that Ekman — the alternative — was planning to campaign for Bjerknes and therefore opposed him in spite of an earlier declaration that Ekman's work stood clearly above Sandström's54.

Oseen also made use of an attack by the volatile Sandström against his friend Bjerknes, written in 1923 at a moment of great personal despair. Sandström's harangue followed an interview with

Royal Meteorology Society: Symons Gold Medal

From Nature of 6 January 1940:

THE decision of the Council of the Royal Meteorological Society to award the Symons Gold Medal for 1940 to Dr J. Bjerknes will be very popular among British meteorologists, to whom he has become well known during his frequent visits to this country. In 1932 the medal was awarded to his father, Prof. V. Bjerknes, and it is fitting that the son, who shared the work, should also share the honours.

In 1933 the accumulated research of the Norwegian school of meteorologists into the dynamics of the atmosphere was published in book form under the title "Physikalische Hydrodynamik" by V. and J. Bjerknes, H. Solberg and T. Bergeron. Dr Bjerknes is still young, and we look forward to further important research in future from these brilliant Norwegians.

Bjerknes carried in the Stockholm daily Dagens Nyheter entitled, "Norway, meteorology's leading nation"55. In a published response, Sandström said that the polar front theory has not been effective in Sweden nor elsewhere, and that the wave-theory of cyclones conflicted with empirical experience in Sweden. He added that "Norwegians are almost too vigorous when it comes to creating new hypotheses and theories, and it is neither desirable nor practical that we follow them in all their capers and flights of fancy [krumsprång och hugskott] of this sort"56. Oseen in his support for Sandström's election to the Klass, claimed therefore that Sandström had during the past few years tested empirically Bjerknes's theories for the polar front and for cyclones, finding that "the first theory is not confirmed by the meteorological phenomena in Sweden while the Bjerknes equations for cyclones do not stand in agreement with the actual [observed] conditions"57. Sandström was elected and Oseen now had a basis for arguing against Bjerknes's candidature. Yet, by the 1930s, most meteorologists were forecasting with the Bergen school's methods and working on theoretical problems associated with them. So Oseen and other committee members who preferred a restricted definition of physics had to find another strategy.

By 1936 the case for awarding a prize to Bjerknes and his chief assistants was strong. Ekman, who supported Bjerknes and who was now a member of the Klass, requested that the committee prepare a special report on Bjerknes, even though C. D. Anderson was "waiting in turn"58. Unable to avoid the issue, Oseen began a detailed report on the Bjerknes school's activities. Apparently, he concluded that regardless of the value of their work, meteorology could not be considered as part of physics, and hence not in the domain for the prize⁵⁹. Ekman protested, asserting that meteorology and weather forecasting, when based on solid physical

principles such as those of Bierknes, perfectly meets Nobel's intentions of both being significant in physics and benefiting mankind60.

Knowing that Oseen dared not try to change the statutes formally to exclude meteorology, Ekman suggested that Oseen should take the matter up before the Academy⁶⁰. Should the committee and the Klass believe Bjerknes worthy, they could propose him for a prize and, also, suggest an alternative candidate within Oseen's "restricted definition of physics". Thus, should the Academy decide that meteorology is not eligible, the committee would still have control over the alternative candidate. In short, Ekman suggested that the Bjerknes case could be a precedent for interpreting the statutes60. But, Oseen did not want to risk having a precedent for meteorology being part of physics. To ensure that the Bjerknes nomination did not reach the Academy, by having it first rejected in the committee or in the Klass, Oseen apparently included in his special report a disparaging personal attack. According to Sandström, who was in the Klass, Bjerknes would have probably received a prize had Oseen not written his 'perfidious Bjerknes biography''61. Oseen seems to have chosen Bjerknes's outmoded interests in physics to discredit him as a scientist. Bjerknes had found it impossible to abandon his father's search for analogies between hydrodynamic and electromagnetic fields of force. As a young man Oseen had also worked in this area. but he now considered these methods and goals of the 1890s to be totally absurd and even contemptible⁶². By portraying Bjerknes as a hopelessly plodding

physicist, who neither accepted nor understood modern physics. Oseen tried to convince the committee and Klass that Bjerknes would be an embarrassment for the Academy. Oseen related how with 'special satisfaction" he could use against Bierknes the latter's belief that Einstein's relativity theory marked the end of classical physics, rather than the start of the new⁶³. Finally, to finish off the Bjerknes candidature Oseen solicited comments from vet another Bierknes assistant, who was then attempting to establish a rival school of meteorology in the United States: "For practical weather forecasting . . . Bjerknes's calculations have absolutely no significance whatsoever''64. Although effective in preventing Bjerknes from receiving a Nobel Prize, this statement, in this form, is false.

Oseen died in 1942 having successfully blocked the awarding of a Nobel Prize for work in the geophysical sciences. His goal of promoting theoretical physics and of improving the international stature of Swedish physics had led him to attempt restricting the definition of physics within the Academy and for the prize. Yet, there is no formal reason based on Nobel's will for excluding geophysics and astrophysics from the prize. Rather, there is only a tradition of interpreting the statutes that has been informed by past personalities and contingencies. Oseen and other committee members recognized this to be true. When Bjerknes confronted him with solid evidence that Nobel considered meteorology and geophysics to be part of physics, Oseen replied that "the interpretation of words changes from person to person. What do we mean by

physics? What do we mean by 'during the preceeding year' or 'recently'? . . . Do any words exist that have a fixed significance?"65. As soon as one finds an interpretation "consistent with one statute, one finds another inconsistent"66.

The summing up

Inevitably, the interpretation of the statutes rests on personal judgement and prejudice. When in 1926, the Klass rebelled against the committee's long-standing rejection of J. Perrin for a prize, Gullstrand insisted, in an attempt to block him once again, that Perrin's work on brownian motion has not benefitted mankind⁶⁷. Recognizing the inconsistent standards used by the committee, Benedicks responded by calling attention to the fact that the committee seemed to use the statutes arbitrarily to dismiss persons they a priori did not want to honour with a prize⁶⁸. Summing up the whole controversy, one member of the committee for chemistry remarked in despair "that to sit on a N[obel] C[ommittee] is like sitting on a quagmire [gungfly] — one doesn't have firm footing under one's feet"69. Similarly, to discuss and to assess the significance of the Nobel Prizes without taking into account the Swedish context is, as well, "att sitta på en gungfly"!

I thank Elisabeth Crawford (CNRS, Paris) for criticism and for access to the manuscript of her book in progress, the Royal Swedish Academy of Sciences for admitting me to their archives, the Norwegian Research Council for Science and the Humanities and Maison des Sciences de l'Homme (Paris) for financial support.

NEWS AND VIEWS

The search for proton decay

from Frank Close

THE discovery that at ultra-high energy, the strong, electromagnetic and weak forces may take on similar behaviours has led to the development of grand unified theories (GUTs) which unite them at 10¹⁵ GeV. The theories predict that, at extreme energies, quarks and leptons assume similar characteristics and can transmute back and forth. At very low energies, such as are present today, these exotic processes are frozen but not totally eradicated. Transmutation of quarks (in the proton) into leptons is predicted to occur, albeit very rarely, causing protons to decay with a half life of about 10³⁰ yr.

The search for evidence of proton decay is one of the most popular topics in highenergy physics and the opening talk at the biennial European Physical Society conference* held in Lisbon last month outlined ten independent such experiments around the world. Three are still proposals, five are being set up, one has put a limit of ≥1030 yr on the lifetime and a Bombay-Japan collaboration has three possible candidate events for proton decays. If these survive, then the future will be very exciting as the proposed experiments should see many scores of events which will not only confirm the proton decay phenomenon but, by studying the nature of its decay products, yield profound insights into the relationship between quarks and leptons.

Studying rare phenomena, such as the cold residue of a high-energy unity, is one way of testing the unified theories. More direct of course is to push laboratory experiments to ever higher-energy regimes and so push nearer to that unity.

H. Schopper, the director-general of CERN, surveyed the planning for high-energy physics facilities until the 1990s. Towards the end of this decade it is hoped that very high-energy annihilations of electrons and positrons may be achieved at Stanford University, California or at the large electron-positron accelerator (LEP)

to be built at CERN, Geneva, which will be able to probe the energy region where the weak force has merged in strength with the electromagnetic. Great excitement was generated by Carlo Rubbia's (CERN) announcement that the first collisions of protons and antiprotons had been achieved in the CERN SPS accelerator, paving the way for producing W and Z bosons there. The optimists hope that the first few events producing these weak interaction quanta may occur by early next year.

The theories of electromagnetic and nuclear forces that have spawned the GUT were reviewed by several speakers. On the phenomenological front, P. Landshoff (University of Cambridge) surveyed the field, concluding that all the data continue to support the Glashow-Weinberg-Salam SU, ×U, model of electroweak forces and the SU, quantum chromodynamic theory (QCD) of quark forces. The obvious qualitative successes of the latter are proving hard to make more quantitative because perturbation theory of quarkgluon interactions converges very slowly. Landshoff reviewed some theoretical attempts to construct approaches to the renormalization of QCD which would improve the convergence properties. This is an area of study that is still in some flux.

R. Marshall (Rutherford Laboratory, UK) exhibited some of the most compelling evidence yet for gluons manifesting themselves as parents of particle jets in electron-positron annihilation data. The electron and positron annihilate producing a quark in one direction and an antiquark and glue centred on the opposite direction. A shower of particles induced by the quark is balanced by two showers symmetric about the 180° axis — the products of (anti) quark and gluon.

F. Close (Rutherford Laboratory) pointed out how just as coloured quarks cluster to form 'white' hadrons, so should coloured gluons cluster to give white glueballs. There has been some speculation that a glueball may have been seen with a mass of about 1,400 MeV (Nature, News and Views 292; 195, 1981). It has also been

suggested that a 2-GeV state seen decaying into two \$\phi\$ mesons may be a glueball; more data from this experiment may elucidate the possibility. At the moment the 1,400-MeV state looks the best bet but, as outlined in *Nature* (292; 195, 1981), there is still much work to be done.

The search for white glueballs as opposed to individual coloured gluons is based on the belief that QCD confines colour in such clusters. G.'t Hooft (University of Utrecht) gave a detailed review of current attempts to prove this and R. Feynman (Caltech) reported his own attempts to prove confinement in a world of two-spatial dimensions.

But are quarks confined? A confrontation took place between W. Fairbank (Stanford University), who has claimed to observe fractional electrical charges on niobium spheres, and G. Morpurgo (University of Genoa), who finds no such phenomenon on iron. The issue was not resolved — Morpurgo's experiment cannot levitate niobium, and Fairbank's cannot levitate iron. Morpurgo may be able to study an 80:20 iron/niobium mixture soon; whether this helps resolve the question remains to be seen. (See Lyons Nature, News and Views 291; 534, 1981 for a discussion.)

Another interesting confrontation between groups with data in prima facie conflict took place. A Bologna-CERN-Frascati collaboration has claimed to produce a baryon containing a bottom (or 'beauty' quark). This state has a mass of 5.4 GeV and, if verified, would be the most massive baryon ever found. The experiment occurred in the split-field magnet at the CERN intersecting storage rings (ISR) and the claimed mass is in excellent agreement with theoretical predictions. However, a collaboration from Annecy-CERN-Paris-Dortmund-Heidelberg and Warsaw reported that they had performed a similar experiment in the same conditions and found no signal.

Frank Close is at the Rutherford and Appleton Laboratories, Didcot, UK.

^{*}The High-Energy Physics European Physical Society conference was held in Lisbon from 8 to 15 July.

Transposable elements and proviruses

from D.J. Finnegan

THE discovery that both prokaryotic and eukaryotic genomes are less stable than classical genetic analysis had indicated is one of the many important developments made in molecular genetics over the past few years. Application of recombinant DNA techniques to the study of eukaryotic genome organization has revealed the presence of transposable elements within the genome of Drosophila melanogaster1-3. These comprise about thirty families of repeated sequences, together making up approximately one-half of the moderately repetitive DNA (5-10 per cent of the total genome) in this species. The best studied families (known as copia, 412, 297, mdgl and mdg3 after the first member of each to be studied) have several properties in common, although there is no detectable homology between them. The members of each family (often referred to generically as 'copia-like' elements) are well conserved and are located at 20-40 sites distributed throughout the genome. The number and locations of elements in each family vary between embryonic and tissue culture cell DNA where there may be up to 250 copies per haploid genome^{2,4}. The number of potential sites must be high and elements may even insert at random.

At both ends of a transposable element are direct repeats (1 in Fig. 1a) a few hundred base pairs long, the length and sequence of which are specific for each family of elements^{5,6}. At the extreme ends of each element are short (about 10 base pairs) inverted repeats (2 in Fig. 1a) which, except in the mdg3 family, occur at both ends of the long direct repeats. Immediately before and after each element is a short direct repeat (3 in Fig. 1a), the length, but not sequence, of which is constant for all members of a particular family (5 base pairs in the case of copia elements). Comparisons between particular sites in the genome from different sources, one containing and one lacking (an 'empty site') a tranposable element, indicate that the bases of the short direct repeat occur only once at the site into which an element inserts7.

The properties of *Drosophila* transposable elements described above resemble those of bacterial transposons⁸. This raises the possibility that, despite no evidence for a direct relationship between the two, *copia*-like elements might be responsible for the same range of genetic events (stable and unstable mutations, deletions, inversions and translocations) in *D. melanogaster* as are transposons in *Escherichia coli*. The most interesting

Fig. 1 a, A transposable element. The various components are: 1, long direct repeat; 2, inverted repeat; 3, short direct repeat. b, Relationship between viral RNA and proviral DNA. U3, unique sequence from the 3' end of the viral RNA; R, sequence repeated at both ends of the viral RNA; U5, unique sequence from the 5' end of the viral RNA.

EMPTY SITE

example of this to date concerns the white eye gene (w). Bingham, Judd and Rubin (Rubin, personal communication) have shown that the white apricot mutation, w^a , is due to insertion of a copia element at the white locus. Some unstable w alleles are also due to insertions, although the sequences involved do not belong to any of the well characterized families of transposable elements (Rubin, personal communication).

The abundance of transposable elements in the genome of *D. melanogaster*, and the fact that their activity can have recognizable genetic consquences, prompt one to ask whether sequences of this type might be found in other eukaryotes. Indeed, a family of transposable elements, *TyI* elements, has been discovered in the yeast *Saccharomyces cerevisiae* and these have properties very similar to those of *copia*-like elements. The same is true of the DNA

proviruses of vertebrate retroviruses.

Cells which have been infected by retroviruses may have one or more copies (proviruses) of the viral genome integrated into their chromosomes. At each end of a provirus are direct repeats, known as long terminal repeats (LTRs). At the left-hand end of a LTR is a unique sequence from the 3' end of the viral RNA. Adjacent to this is the sequence repeated at both ends of the RNA and a unique sequence from its 5' end. These are shown in Fig. 1b where they are designated U3, R and U5 respectively. After infection of a host cell, viral RNA molecules are first copied into linear double-stranded DNAs with a LTR at each end. These are then converted into circular molecules with either one copy of the LTR or two copies in tandem. It is not known which of these DNAs integrates into host chromosomes but some evidence favours a circular form (for detailed

D

D.J. Finnegan is in the Department of Molecular Biology, University of Edinburgh.

discussion, see ref. 9). The sequence organization of proviruses resembles that of Drosophila transposable elements in several ways10. They have short inverted repeats at their ends and are flanked by a direct repeat of a few base pairs which occurs only once at the site of insertion in their absence (Fig. 1b).

Vertebrates do not have to be infected by retroviruses to acquire sequences of this type. The genomes of most, if not all, vertebrates contain endogenous proviruses, which can make up a substantial proportion of their DNA (about 0.1 per cent in primates and rodents)11. Like Drosophila transposable elements, the chromosomal locations of endogenous proviruses differ between individuals in populations of mice and chickens. The topographical similarities between proviruses and transposable elements suggest that they may be related and Temin¹² has argued that proviruses evolve from transposable elements. If this is the case, one might expect to find within D. melanogaster cells circular DNAs similar to extrachromosomal proviral DNA. Circular DNAs were detected in D. melanogaster embryos and tissue culture cells some time ago and have been shown to be largely comprised of repetitive sequences¹³. In a recent issue of *Nature* (292; 591, 1981), Flavell and Ish Horowicz described their attempts to find molecules with copia-specific sequences amongst these circles. They have been able to purify three different circular DNAs of this type from D. melanogaster tissue culture cells using ethidium bromide-caesium chloride density centrifugation and DNA cloning techniques. On the basis of their restriction site maps two of them do appear analogous to circular proviral DNA, having all the sequences from the body of a copia element plus one copy of its long direct repeat or two repeats in tandem. The third class appears to be a deletion derivative of one of the other two.

Stimulating though these observations are, they do not clarify the relationship between transposable elements and retroviruses since (as Flavell and Ish Horowicz point out) these circular molecules need not be produced by reverse transcription but could be formed by

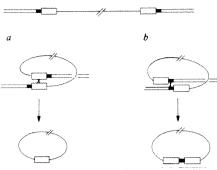

Fig. 2 Recombination in a transposable element: a, between the long direct repeats at the ends of an element, giving a circular molecule with one copy of the direct repeat, and b, between the 5 base pairs on either side of the element giving a circular molecule with two copies of the direct repeat.

recombination. Recombination between the long direct repeats at the ends of a transposable element would yield a circular molecule with one copy of the direct repeat (Fig. 2a) whereas recombination between the 5 base pairs repeated on either side of a copia element would yield a circular molecule with two copies of the direct repeat in tandem (Fig. 2b). These possibilities should be distinguished by DNA sequence analysis of the circular molecules with two copies of the long direct

repeat. If they are derived recombination, then the two repeats should always be separated by 5 base pairs but a different 5 base pairs in each case; if they are derived by reverse transcription of full-length copia RNA, then all circles with two repeats should be identical. Whatever their origin these circles could be intermediates in transposition, a possibility which Flavell and Ish Horowicz are investigating.

The sequences discussed so far are not the only ones involved in DNA rearrangements. Potter and his colleagues have found transposable sequences in D. melanogaster with properties distinctly different from those of copia-like elements and specific, rather than random or semirandom, rearrangements have been demonstrated for genes controlling mating type in S. cerevisiae, surface antigens in trypanosomes and immunoglobulins in mammals. Others may exist, but one should be wary of getting too carried away by these results. Eukaryotic genomes are more labile than has been generally supposed but wholesale rearrangements do not occur. In Drosophila, genes still retain their order in linkage groups, this order is the same in somatic and germ-line cells, and the banding pattern of polytene chromosomes is remarkably constant.

The expanding use of potential-sensitive dyes

from a correspondent

THE recent paper in Nature reporting the use of a voltage-sensitive dye to localize pacemaker activity in early embryonic heart is a good example of the expanding interest in and application of potentialsensitive dves for biological, electrophysiological and biophysical studies. Cyanine, merocyanine and oxonol dyes respond spectrally to potential changes in, for example, squid giant axon^{2,3}, red blood cells⁴⁻⁶, black lipid membranes7, frog skeletal muscle8 and frog heart9

The available probes are of two general types: those which permeate the cell membrane and have both slow and fast responses (for example, carbocyanines) and non-penetrating dyes with only fast signals, of which merocyanine-rhodanine used by Kamino et al. is a good example. As reviewed recently by Waggoner¹⁰, the slow dyes, with their large responses, seem ideally suited for following the kinetics of potential changes that occur in times of a few seconds, whereas the fast probes can resolve adequately events associated with membrane excitation during action

potentials, although their absorption and fluorescence changes are usually only 0.001 to 1 per cent. The slow (or redistribution or accumulation) dyes operate by potential-dependent mechanisms redistributing the charged dye between extracellular and intracellular environments of the cell, organelle or vesicle, whereas optical signals from rapidly responding dyes occur through potentialdependent changes of dye molecules located on (or very near) the membrane.

There are obvious attractions in using these optical probes, especially in cells which are too small to be examined by classical microelectrode techniques, or in complex cellular networks where multiple and accurate impalements would be very laborious and difficult. However, it has long been recognized that care has to be taken in both interpreting experimental data, hence the comforting corroboration in squid axon where parallel membrane potential measurements can be made with confidence, and ensuring that introduction of the dye does not in itself perturb the preparation. Permeant dyes can inhibit

intracellular metabolic processes and the binding of charged dve molecules might interfere with important membrane processes mediating biological responses. In addition, dyes may react with the exogenous reagents, whose effects are being examined, to form non-fluorescent complexes. This would make doseresponse curves difficult to interpret and would complicate kinetic calculations. Furthermore, even with modest illuminations, some dves can cause cellular photodynamic damage. These considerations have prompted intensive work to produce dyes with better responses and biological inertness.

It is possible to end on an optimistic note, for recent reports (to quote but two examples) have described how potentialsensitive dyes can be used to advantage to monitor either mitochondrial membrane potentials¹¹ or radial propagation along muscle fibre T-tubules¹². These, together with the elegant studies of Kamino, Hirota and Fujii¹, suggest that such techniques have an important future in many investigations involving molecular mechanisms at the cellular level.

The evolution of sedimentary basins

from C.A. Williams

THE selection of 'The evolution of sedimentary basins' as the topic for a Royal Society discussion meeting* reflects the impetus given to the field by new models of basin formation, in particular the crustal stretching model of McKenzie, and by the availability of quantitative data on crustal loading and flexure which are allowing models to be tested. The McKenzie model (Earth planet, Sci. Lett. 40; 25, 1978) proposes that sedimentary basins are formed by rapid stretching of the continental lithosphere by normal faulting, instigated by a passive upwelling of hot asthenospheric material beneath the crust. Once the thermal stage has passed, the lithosphere thickens as the heat is conducted to the surface and undergoes a slow subsidence which is not associated with faulting and which may be amplified by sediment loading.

The meeting made no attempt to cover all types of basin, but concentrated on those where good-quality data are available. Discussion of continental margin basins was dominated by contributions on the Biscay margin (presented by D.G. Roberts, IOS, and J.-P. Foucher, CNEXO, Brest), largely based on the results of IPOD drilling on the North-west Biscay margin and on associated seismic reflection and refraction data. Both Roberts and Foucher showed seismic reflection evidence of listric faults dipping consistently oceanwards. These two

studies, whilst producing the most detailed information we yet have on this margin, also indicate the limitations of fragmentary evidence in reassembling faulted strata. Robert's interpretation requires infinite stretching of the lower crust but less stretching in the upper crust than that required by Foucher's interpretation, yet both studies are based on essentially the same data set. The range of disagreement is such as to encourage the acquisition of more and better data to allow more accurate estimation of fault displacements.

The continental margin basin section was completed by an exposition of the North-west Australian margin by D.E. Powell (Hudbay), a margin remarkable in that the basins seem to be related to the late Palaeozoic phase of abortive rifting with little or no modification during the eventually successful rifting in the early Cretaceous.

An intriguing puzzle came from discussion of intracontinental basins. There appear to be two types of basement beneath basins, one in which normal faulting occurs as expected; but in cratonic shelf basins, for example, Witwatersrand, Transvaal and Michigan Basins, the basement does not appear to be normally faulted and some other mechanism of basement subsidence, other than extension by faulting, must be evoked. The Michigan Basin, nonetheless, shows the same exponential subsidence as other basins and the existence of COCORP seismic reflection data across it suggests a clear line of future study into the apparent lack of basement faulting.

In the session on basin formation, A.B. Watts (Lamont-Doherty Geological Observatory) discussed the role of crustal flexure, showing that this becomes a major factor in basins more than 200 km wide and that the best overall fit to the observations is an elastic plate model with crustal strength increasing with age. This predicts a sedimentary geometry with coastal onlap and it seems that Vail's eustatic sea-level changes based on evidence of onlap may in reality be a record of basin subsidence. The thermal effects of subsidence were discussed by D.L. Turcotte (Cornell University) (all basins appear to be initiated by a thermal event), while C. Beaumont (Dalhousie University) compared foreland and Atlantic-type basins and concluded that the major contrast is the thermal age of the lithosphere. The old, cooler and thicker lithosphere of the foreland compressive area will respond to loading with greater rigidity and depression wavelength than the younger, hotter, thinner and less rigid rifted continental margin basin.

Some of the outstanding problems in understanding sedimentary basin subsidence, in particular the origin of tensile stresses in the crust which initiate the normal faulting, were discussed by M.H.P. Bott (Durham University). Their origin may be found in stresses at convergent plate boundaries, hence, for example, the origin of the Northern European Carboniferous basins may be related to stress fields in operation during the subduction of the Hercynian Ocean.

In summarizing the meeting, A.W. Bally (Shell) cautioned that the folded belts, for example Zagros, Franklinian Basin and the Precambrian basins, are too complicated for modelling with currently available data. The complexity of listric faulting causes inherent problems in estimating fault displacement. While in some spectacular cases the sole of the listric fault has been observed, more high-quality seismic data across basins are required for better evidence of the actual existence and shape of listric faults. The question of whether symmetric graben are purely a function of geological imagination was also raised, since observed graben are either asymmetric or exist as half graben.

The general conclusion was that the stretching model gives a reasonable explanation of the formation of many basins. It was a little disappointing that among the excellent and often complicated stratigraphical histories described in oil-company presentations, studies on subsidence, flexure, fault displacements and so on were not emphasized, leaving one to wonder whether the oil companies are way ahead in considering these effects in a quantitative way, though refrained from divulging same, or whether in fact it is the academics who are leading in this area.

^{*}The meeting was organized by Sir Peter Kent, M.H.P. Bott, D.P. McKenzie and C.A. Williams and the proceedings will be published in the *Philosophical Transactions of the Royal Society*, January 1982.

Membrane manoeuvres in Marseille

from R.C. Hider

Most animal and bacterial toxins are directed against membranes, the more toxic interfering with critical receptor proteins while others are highly efficient lytic agents. The former, by virtue of their high-affinity interactions, have been used as probes in developmental and physiological studies and the latter, because of their affinity for lipids, are used in the elucidation of the molecular organization of membranes. A number of recent developments in these fields were reported at a meeting of the International Society of Toxinology* where discussions centred on the sodium channel, the cholinergic synapse and cytolytic toxins formed the framework of the meeting.

The sodium channel

The voltage-dependent sodium channel, a prime constituent of excitable membranes, remained firmly out of the biochemist's reach until the discovery of channel-specific toxins. Since 1970 however, the concerted application of tetrodotoxin, saxitoxin, scorpion and sea anemone toxins has given reliable information on the distribution, density and unit ion flux of

*The Fourth European Symposium on Animal, Plant and Microbial Toxins (24-27 June 1981) was organized by Hervé Rochat, Faculté de Medécine Sectear Nord, Marseille. The proceedings of the meeting will be published by Pergamon Press in 1982.

various sodium channels. As reported by V. Berwald-Netter (Collège de France, Paris) and J.F. Renaud (Centre de Biochimie, Nice), the development of these channels in embryonic tissue can also be monitored as sea anemone and scorpion toxins bind to both silent and functional channels1 and can give a quantitative index of neuronal maturation². W.A. Catterall (University of Washington, Seattle) reported the isolation of a functional sodium channel from mammalian brain³ but instability of the preparation — its lifetime is limited to 3 days — is a major problem. As with other membrane protein isolation procedures, the presence of a protease inhibitor cocktail has been essential, Catterall's laboratory including o-phenanthroline. This powerful chelator removes essential cationic cofactors from proteolytic enzymes and yet leaves calcium in solution to enhance the stability of the isolated channel. Catterall reported that the membrane channel consists of two proteins of molecular weights 270,000 and 37,000, both being specifically labelled by photoaffinity-tagged sea anemone toxin. The nature of the large subunit, which has also been reported elsewhere4, is of great interest. Does it consist of subunits crosslinked by functional groups other than disulphide fuctions? Does calcium

modulate its conformation? Whatever the answers to these questions, its isolation in a functional state marks the beginning of a new era which is likely to be centred on precise electrophysiological experiments with well defined reconstituted bilayer membranes.

There was general agreement at the meeting that the 'old world' scorpion neurotoxins bind to the sodium channel in a voltage-dependent manner and thus interact with a component capable of existing in two conformational states, the relative proportions of which depend on membrane potential⁵. However, the 'new world' scorpion toxins lack this property and bind to a different site on the sodium channel⁶. The three-dimensional structure of one such toxin (from Centruroides sculpturatus) was shown by J.C. Fontecilla (Aarhus University) to possess an extensive backbone of secondary structure crosslinked by four disulphide bridges7. Emerging from this relatively rigid structure are two peptide loops which are believed to interact with the receptor. On the basis of secondary structure predictions, Fontecilla suggested that both

"How I crossed Africa, from the Atlantic to the Indian Ocean" By Major Serpa Pinto (London: Sampson Low & Co., 1881)

To cross Africa has almost ceased to be an extraordinary feat. Indeed it seems evident, the more we know of the Portuguese native traders, that even before Livingstone's memorable first journey, it was no uncommon thing for the Pombeiros to do in the ordinary way of business. Of course some routes are more dangerous than others, and that by which Stanley made his famous march was perhaps the most difficult and dangerous that could be selected. Still the journey performed by Major Serpa Pinto was in many ways remarkable, and perhaps not its least remarkable feature is the characteristic manner in which he tells his story.

One of our illustrations gives a good idea of an antelope which was met with in the Cuchibi, which the Major thus describes:

"At one of the turns of the river I perceived three antelopes of an unknown species, at least to me; but just as I was in the act of letting fly at them they leaped into the water and disappeared beneath its surface. The circumstance caused me immense surprise, which was increased as I went further on, as I occasionally came across several of these creatures, swimming; and then rapidly diving, keeping their heads under water, so that only the tips of their horns were visible. This strange animal bears among the Bihenos the name of Quichôbo. Its life is in a great measure passed in the water, it never straying far

The Quichôbo

from the river banks, on to which it crawls for pasture, and then chiefly in the night-time. It sleeps and reposes in the water. Its diving-powers are equal, if not superior, to those of the hippopotamus. During sleep it comes near to the surface of the water, so as to show half its horns above it. It is very timid by nature, and plunges to the bottom of the river at the slightest symptom of danger. It can easily be captured and killed, so that the natives hunt it successfully, turning to account its magnificent skin and feeding off its carcase, which is however but poor meat. Upon leaving the water for pasture its little skill in running allows the natives to take it alive; and it is not

dangerous, even at bay, like most the antelope tribe. The female, as well as the male, is furnished with horns. There are many points of contact between the life of this strange ruminant and that of the hippopotamus, its near neighbour. The rivers Cubangui, Cuchibi, and the upper Cuando offer a refuge to thousands of Quichôbos, whilst they do not appear either in the lower Cuando or the Zambesi. I explain this fact by the greater ferocity of the crocodiles in the Zambesi and lower Cuando, which would make short work of so defenceless an animal if it ventured to show itself in their waters."

From Nature 24, 7 July, 215, 1881.

classes of toxin have similar shapes but differ in the relative lengths of the peptide loops emerging from the conserved framework. Why these relatively minor differences are associated with the presence or absence of voltage-sensitive binding is not clear but it would be interesting to study their relative affinity for the 37,000-molecular weight protein identified by Catterall.

The cholinergic synapse

There is now general agreement on the structure of the Torpedo (electric ray) acetylcholine receptor. In his review, J.P. Changeux (Pasteur Institute) reported that the basic functional unit, as judged by reconstitution experiments, is composed of four polypeptide subunits of molecular weights 40, 50, 60 and 65×10^3 respectively, the latter three being extremely susceptible towards proteolysis. The 40,000molecular weight protein is the site of agonist (acetylcholine) and antagonist (curare and elapidae snake toxin) binding. Exactly how the snake neurotoxins interact with the 40,000-molecular weight subunit is unknown and this uncertainty severely limits their use as affinity ligands. However the problem is being energetically attacked by the Russian group led by F. Bystrov and V. Tsetlin (Shemyakin Institute), who are applying ESR, NMR and photoaffinity labelling techniques to monitor the toxinreceptor interaction8. A 43,000-molecular weight subunit, which is also associated with the receptor, has been shown not to be essential for acetylcholine receptormediated cation translocation9 but is thought to have a structural role, crosslinking receptor rosettes into the characteristic double rows often seen in electron micrographs 10.

Presynaptic phenomena are not so well characterized at the molecular level as are the corresponding postsynaptic events, but J.O. Dolly (Imperial College, London) and A.L. Harvey (University of Strathclyde) reported two new approaches designed to tackle this problem. Dolly described a method for the purification and iodination of botulinum toxin which specifically inhibits the release of acetylcholine¹¹ and Harvey demonstrated that Kunitz-type protease inhibitor homologues, isolated from the venom of *Dendroaspis* snakes (mambas), dramatically stimulate acetylcholine release¹². Significantly, as judged from pharmacological studies, these inhibitor-like polypeptides compete with β -bungarotoxin (from krait venom) for a common binding site on the presynaptic membrane. β -bungarotoxin is used extensively by physiologists and consists of two polypeptides, the A chain, a phospholipase, and the B chain, a protease inhibitor homologue. Thus it seems likely that the B chain directs the phospholipase activity of the A chain to the presynaptic membrane. Both botulinum toxin and protease inhibitor homologues would appear to have potential as specific presynaptic probes, as unlike the toxins currently used, they lack phospholipase activity. Development of new antivenins

In many meetings devoted to neurotoxins, there is often a tendency to forget that snakes and scorpions can present serious health hazards. Each year 1,000 people die in Mexico from scorpion stings and 2,500 people die in South-east Asia from snake bites¹³. Some of the symptoms associated with such poisoning were vividly presented in a session devoted to the clinical aspects of envenomation which was chaired by H.A. Reid (Liverpool School of Tropical Medicine and see ref. 14). The efficiency of antivenoms is likely to improve now that new techniques have been developed to produce antibodies specifically directed against the most toxic components of the venom. One such example was reported by J.C. Boulain and A. Menez (CEN Saclay, France) where the production of a monoclonal antibody directed against a cobra neurotoxin was described. Combinations of such antibodies directed against different snake neurotoxins should produce efficient antivenoms for specific geographical localities and thus, in principle, a comprehensive range of such antivenoms could become available for world-wide distribution.

Cytolytic toxins

Cobra venoms, in addition to containing postsynaptically acting neurotoxins, possess an even higher content of so-called 'cardiotoxins'. This term, although widely used, provides too narrow a label as these polypeptides depolarize all muscle types and many also possess lytic properties. Indeed, as described by D.S. Chapman (Ashington, Northumberland, UK), cytotoxicity and not neurotoxicity is the dominant symptom of Naja nigricollis (spitting cobra) envenomation. J. Dufourcq (Talence, France) eloquently described the interaction of these hydrophobic proteins with negatively charged lipids, showing how they induce lipid phase separation, and R. Hider (University of Essex) demonstrated that some toxins which possess powerful cardiotoxic properties lack lytic properties, arguing against the view that the muscle-depolarizing ability is directly associated with non-

specific lytic properties. In the past much of this work has been bedevilled by contaminating traces of phospholipase, which can endow the preparation with lytic activity. H. Veheij (University of Utrecht) reviewed the chemistry of phospholipase-A, molecules, indicating how the increased content of surface aromatic side chains is associated with improved powers of membrane penetration. Presumably the tight association between these enzymes and the hydrophobic cardiotoxins results from a similar interaction. Immunoaffinity chromatography is an excellent method for removing traces of phospholipase¹⁵ and probably should be used routinely in the isolation of this class of protein.

R. Mollby and M. Thelestam (National Bacteriology Laboratory and Karolinska Institute, Stockholm) described how their fibroblast-based analytical system permitted the classification of cytolytic toxins16. Their data formed a useful background for the classification of toxins isolated from Aeromonas hydrophila (Gram-negative rod bacterium) and the socalled thiol-activated cytolysins. However it was clear from the meeting that the mode of action of many of these toxins is not understood. The colicins A, E, I and K were reported by F. Pattus and C. Lazdunski (University of Marseille) to form voltage-dependent channels in bilayer membranes, in a similar manner to the lytic peptide alamethicin¹⁷. In this context, J.H. Freer (University of Strathclyde) tentatively suggested the existence of an oligomeric pore structure for staphylococcal δ-lysin and R. Hider (University of Essex) made a similar suggestion for bee venom melittin. The lipophilic portion of most plasma membranes is 3 nm thick and thus can be spanned by a 21-residue α -helix. As alamethicin (20 residues), δ-lysin (26 residues) and melittin (26 residues) can all form amphiphilic helices, toxin aggregates could readily form hydrophilic pores capable of spanning a membrane. Significantly, the average number of residues in each of the seven bacteriorhodopsin α -helices is 25 (see ref. 18). Thus in principle, cytolysin oligomers could form bacteriorhodopsin-like structures. If calcium entered or magnesium left the cell via such channels, intracellular proteases would be activated, inducing dramatic effects on the cell membrane¹⁹. Ion specificity of such a channel would be controlled by both the diameter of the aqueous channel and its net charge, and as such could be related to the Mollby-Thelestam classification scheme. Ion specificity of such oligomeric structures will be of considerable interest.

The success of this meeting was, to a large extent, due to the International Society of Toxinology attracting, and thus facilitating, interaction between scientists from an extremely wide range of disciplines. As toxin chemistry and biochemistry continue to expand, so will this Society.

Three myosin heavy-chain isozymes appear sequentially in rat muscle development

Three different heavy-chain isozymes of myosin appear sequentially in rat muscle during the period from late gestation to about three weeks of age. In part these changes can be related to changes in innervation taking place during this period.

THE myosins found in both muscle and non-muscle cells comprise a family of proteins having similar native structures and subunit compositions¹⁻⁴. The myosin isoenzymes in adult skeletal muscle can be classified into two major types. A myosin capable of rapid ATP hydrolysis is characteristic of fast contracting muscle fibres while a myosin of lower ATPase activity is found in slow-contracting fibres⁵. These fast and slow isoenzymes differ in both their heavy- and light-chain subunits. It has been shown⁵ that the maximum speed of shortening of adult muscles is closely correlated to the rate of hydrolysis of ATP by myosin. Therefore the type of isoenzyme present in a muscle can be of physiological importance^{5,6}.

The muscles of newborn animals contract slowly although they may become fast-contracting in the adult⁷⁻⁹. Previous results¹⁰⁻¹⁶ have suggested that slow myosin heavy chain was a major constituent of developing muscle, whereas others report the presence of fast myosin¹⁷⁻²¹ (see also discussion in refs 22, 23).

Recent biochemical and immunological studies have however shown that fetal and newborn skeletal muscles contain certain myosin subunits distinct from the adult forms 24-27. In the case of the myosin heavy chain, the adult forms are not detected as major components of fetal muscle or cultured muscle cells 25-27. To characterize the developmental changes in more detail, we have investigated the types of myosin heavy chains found at various times after birth in rat skeletal muscle destined to become the fast-contracting type. We used various approaches, including polypeptide mapping, complement fixation, immunocytochemistry, gel electrophoresis of native myosins, and the study of synthetic myosin thick filaments by electron microscopy. Our results provide evidence for the sequential appearance of at least three heavy-chain isozymes during muscle development.

Polypeptide mapping of the myosin heavy chains

The large size of the myosin heavy chain $(200,000\,M_{\rm r})$ allows it to be cleaved into many polypeptide fragments which are conveniently analysed by standard one- or two-dimensional gel electrophoresis (ref. 27 and refs therein). However, partial proteolytic cleavage of native myosin is influenced by divalent cations²⁸, by phosphorylation of the LC2 light chain²⁹, and by interaction with actin³⁰ and presumably other proteins. It is thus important to denature the myosin preparations before partial proteolysis to minimize influences other than that of the primary structure on the cleavage of the heavy chain. Proteolysis of SDS-denatured myosin suggests that neither the presence of the light chains nor the presence of another myosin species

influences the cleavage of a given heavy-chain type (ref. 27 and S.M.S. and R.G.W., in preparation). This approach has therefore been used to examine the myosin heavy chains present in rat muscle development.

Figure 1 (upper) shows the heavy-chain degradation pattern produced by chymotryptic treatment of various myosins from cultured cells (L6) or fetal, newborn and adult muscle tissue. From about 19 days after birth, the myosin heavy-chain cleavage pattern is indistinguishable from that shown by adult fast myosin. As described previously²⁷, a distinct embryonic myosin heavy chain (MHC_{emb}) can be found in cultured muscle cells and fetal muscle tissue. However, during the first two weeks after birth another heavy chain isozyme appears which differs in its degradation pattern from both the embryonic form and the adult fast and slow forms. We will refer to this isozyme appearing in the neonatal period as MHC_{neo}.

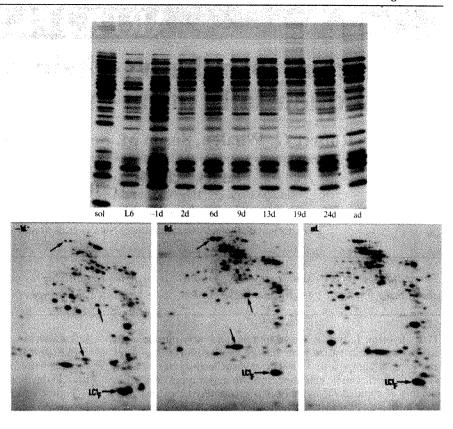

The cleavage pattern produced by the neonatal myosin preparations is unique, as the two-dimensional gel analysis of the chymotryptic polypeptides illustrates (Fig. 1, lower half). This high-resolution analysis shows that the cleavage pattern of neonatal heavy chain is qualitatively different from that of either MHC_{emb} or fast myosin heavy chain (MHC_F). Some characteristic MHC_{neo} polypeptides are shown by arrows in Fig. 1 (lower half). The myosin from fetal tissue (-1 day) contains some MHC_{neo} (arrows; see also Fig. 4). The two-dimensional polypeptide map of MHC_{neo} bears no resemblance to that of the adult slow heavy chain (compare with Fig. 3 of ref. 27). The cleavage pattern of MHC_{neo} is unlike that of any other adult skeletal or cardiac muscle myosin that we have examined nor is it homologous to non-muscle heavy chain (S.M.S. and R.G.W., unpublished observation).

Immunological studies on developmental isozymes of myosin

Complement fixation has been used as a means of measuring the extent of cross-reactivity of a given antibody with different myosins^{27,31-35}. Previous work has shown that the myosin subfragment, heavy meromyosin (HMM), denatured with SDS before injection, produces antibodies with considerable muscle-type specificity. This specificity is greater than when the HMM is injected in its native state^{27,35}. Thus antibodies to SDS-denatured HMM prepared from 8-day old rats were raised in guinea pigs.

In our experiments we used antisera from two different guinea pigs. These anti-neonatal myosin sera react predominantly with the heavy-chain component; this was verified by testing the sera against myosin or crude myosin-containing extracts after separation by SDS-gel electrophoresis and transfer to nitrocel-

Fig. 1 Polypeptide mapping of various myosins. Myosins were prepared as previously described2 , the final step being purification on a Sepharose 2B column in the presence of ATP. Myosin was prepared from the adult soleus muscle (sol) as an example of slow myosin, and from L6 cells as an example of a myosin containing the embryonic heavy chain (see text). The remaining myosins were prepared from the hind leg muscles of adult rats (ad), the soleus muscle being deliberately excluded, or from rats at various stages of development (day -1 is 20 days of gestation; the other numbers indicate days after birth). The proportion of slow myosin in the adult hind leg muscle preparations did not exceed 5%, as determined by electrophoretic analysis of native myosin (see Fig. 4 legend). In the upper part of the figure, analysis was carried out on a one-dimensional SDS gel composed of 12.5% (w/v) acrylamide and 0.1% (w/v) bisacrylamide. Myosins (0.4 mg ml^{-1}) were digested with chymotrypsin (108 µg ml⁻¹) for 30 min at 37 °C as described previously²⁷, and 16 µg of each degraded myosin was loaded on to the gel. In the lower part of the figure, 60 µg of chymotryptic cleavage products were analysed on twodimensional gels. For these experiments, the concentration of myosin was 1.2 mg ml that of chymotrypsin 300 µg ml⁻¹. ampholytes in the isoelectric focusing gel were composed of 1.6% (w/v), pH 5-8 and 0.4% (w/v), pH 3-10, and the second dimension slab gel was 12.5% (w/v) acrylamide and 0.1%

(w/v) bisacrylamide. Two-dimensional gel electrophoresis was carried out as in ref. 24 with the modifications described in ref. 51. The position of the highest molecular weight light chain, LC1_F, is shown for reference as the extent of migration varied slightly among the different samples. Unlabelled arrows indicate characteristic polypeptides of the neonatal heavy chain which are also present in small quantities in the -1 day myosin sample.

lulose paper³⁶ (A.-M. Lompré and K. Schwartz, unpublished results). The myosins to be used as test antigens in the complement fixation reaction were purified on Sepharose 2B columns²⁴, denatured with SDS and mercaptoethanol by heating, and the excess SDS removed as described previously³² These myosins were reacted with the antisera at dilutions chosen to give $\sim 60-70\%$ complement fixation with the homologous antigen (myosin from 10-day old animals). When the antisera were tested with myosin from adult fast muscle, fetal muscle tissue or from L6 cells, the amount of complement fixed was considerably less than in the case of the neonatal myosin (Fig. 2). This result illustrates that there are quantitative antigenic differences between the various myosins, although they share some common determinants. The absence of a reaction for L6 myosin at the dilutions shown does not indicate a total lack of cross-reactivity; if the neonatal myosin antibodies are simply concentrated then a positive reaction can be obtained for the L6 myosin which differs quantitatively from that given by the homologous antigen (result not shown; see also ref. 27). The myosin from fetal muscle tissue gives greater complement fixation than does L6 myosin due to the presence of MHC_{neo} in the tissue preparations (see Figs 1, 4).

These results show that neonatal myosin differs immunologically from both adult myosin and the embryonic form found in fetal muscle tissue and L6 cells. Together with previous results which show immunological differences between L6 and adult myosin²⁷, this approach distinguishes between the three myosins containing MHC_{emb}, MHC_{neo} and MHC_F.

Antibodies to adult fast and slow myosin were also used in indirect immunofluorescence assays on sections of the gastrocnemius muscle of 7-8-day old rats. Most of the fibres in such muscles are stained when reacted with the antibody to adult fast myosin (Fig. 3a). When this antibody is absorbed with myosin extracted from neonatal muscle (see Fig. 3 legend for details), the fluorescence reaction with the neonatal muscle sections is diminished as expected (Fig. 3b). When used at the same dilution, this absorbed antibody will still react with the fast fibres

of the adult diaphragm (Fig. 3c). These results show that the unabsorbed anti-fast myosin antibody cross-reacts with neonatal myosin but that these cross-reacting antibodies can be removed without totally abolishing the reaction with adult fast myosin. An antibody to adult cardiac myosin which cross-reacts extensively with slow-twitch skeletal myosin^{27,35} was used as a probe for slow myosin-containing fibres. Few fibres stained brightly (Fig. 3d); the proportion of positive fibres varied according to the region of the muscle examined. These immunocytochemical results thus completely agree with the

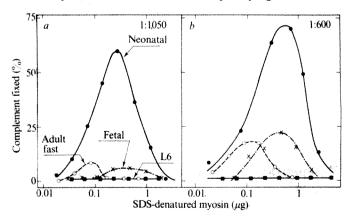

Fig. 2 Complement fixation reactions using antisera to neonatal myosin. Heavy meromyosin (HMM) was prepared from the myosin extracted from the hind leg muscle of 8-day old rats³³. The HMM was denatured with SDS and the excess SDS removed on a G-10 column as described elsewhere³² before injection into five guinea pigs. Four animals developed antibodies; the results shown here are for two of these antisera. The test antigens were prepared from adult muscle (adult fast, ○), muscle of 10-day old animals (neonatal, ♠), muscle from animals at 20 days of gestation (fetal, ×) and from fused cultures of L6 cells (L6, ■). Each test antigen was denatured with SDS and the excess SDS removed on a G-10 column³² before reaction in the complement fixation test^{33,35}.

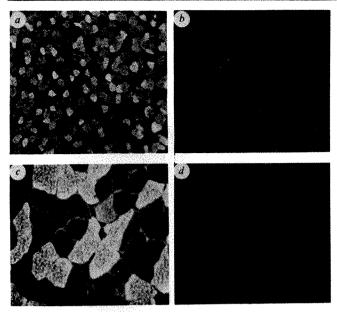

Fig. 3 Immunocytochemical reactions of neonatal and adult muscles. Indirect immunofluorescence was carried out using antibodies prepared in guinea pigs. A fluorescein-labelled goat antiguinea pig immunoglobulin antiserum (Nordic) was used as the second antibody. In a, an antibody to adult fast myosin³⁵ was reacted at a dilution of 1:100 with a section of 7-day gastrocnemius muscle. The anti-fast antibody was also absorbed with myosin prepared from neonatal muscle by first mixing the myosin and antiserum in 0.6 M NaCl and then dialysing to low ionic strength to precipitate the myosin. In b, this absorbed antibody was reacted at a dilution of 1:40 with the 7-day gastrocnemius muscle. In c, the 1:40 diluted absorbed antibody was reacted with a section of adult diaphragm; it reacts with those fibres that react as fast fibres in histochemical staining (results not shown). d, The 7-day gastrocnemius muscle was stained with an antibody to adult cardiac myosin^{27,35}

polypeptide mapping and complement fixation experiments in that they show differences between neonatal and adult myosins.

Electrophoresis of native myosins

The various myosin preparations were further investigated by gel electrophoresis in native conditions^{37,38}; L6 myosin (containing MHC_{emb}) gave only one band (Fig. 4). This same band is found in extracts of fetal tissue at 3 days before birth. Two days later, and in the first few days after birth, another band is present which is distinct from that containing MHC_{emb} (see also the results for the mixture of L6 myosin and a 10-day preparation); this corresponds to the appearance of myosin containing MHC $_{\rm neo}$ (Fig. 1). In the second week after birth, three bands are seen for neonatal myosin; the presence of three bands at this time is probably due to the formation of isoenzymes based on light chain content^{25,39}. From about 14 days onward, the adult fast myosin bands can be seen. The adult slow myosin isozymes are clearly separated from the embryonic, neonatal and adult fast forms (Fig. 4). This analysis confirms the time course of the developmental sequence observed using the polypeptide mapping approach (Fig. 1).

Formation of synthetic myosin filaments

The size and structure of synthetic thick filaments formed from adult fast skeletal myosin depends critically on the relative concentrations of ATP and Mg²⁺ in the dilution buffer⁴⁰. We have therefore compared the effect of these parameters on the formation of synthetic filaments obtained from myosins containing the embryonic, neonatal and adult fast and slow heavy chains.

Synthetic filaments were formed by controlled dilution of myosin and were examined by electron microscopy as previously described⁴⁰. In these experiments, the concentration of ATP in the diluting buffer was kept constant at 0.1 mM and the

 ${\rm Mg}^{2^+}$ concentration varied between 0.1 and 10 mM. Electron micrographs of the various types of filaments obtained from neonatal myosin are shown in Fig. 5a-c. Depending on the concentration of ${\rm Mg}^{2^+}$, three types of filaments were observed. At intermediate concentrations bipolar filaments with tapering ends and constant diameters of 15-20 nm were found (Fig. 5a). This type of filament is structurally similar to natural ones isolated from adult fast skeletal muscle 40.41. At high concentrations of ${\rm Mg}^{2^+}$, thicker spindle-shaped filaments up to 50-60 nm in diameter were formed (Fig. 5b). At low concentrations of ${\rm Mg}^{2^+}$, thin branched structures, ~5-7 nm wide were observed (Fig. 5c). The neonatal myosin filament preparations thus behave qualitatively in the same way as those of adult fast myosin 40.

The concentration range over which these types of filaments were found differed for the several myosins tested (results shown schematically in Fig. 5, lower left). Both fast and slow adult myosins form bipolar filaments with constant diameters over a similar, large concentration range (0.5-10 mM Mg²⁺). The Mg² values at which such bipolar filaments are found is narrow for neonatal myosin and is particularly restricted with L6 myosin. In the latter case, homogeneous populations of bipolar filaments with constant diameters were rarely obtained. Furthermore, the lengths of the bipolar filaments formed in the presence of 2 mM Mg2+ differed for the various myosins (see histogram, Fig. 5, lower right). Both adult fast and slow myosin formed very long filaments (5-7 µm), longer in fact than natural filaments from fast muscle, which are 1.6 µm long41. Neonatal myosin formed filaments of intermediate length (2-4 µm) and L6 myosin only very short ones ($<1 \mu m$).

The formation of myosin thick filaments is due to the aggregation of the heavy-chain subunit, in particular the C-terminal α -helical portion. It has been suggested that the LC2 light chain might influence filament formation 42.43. In adult fast, neonatal and L6 myosins, the LC2 light chain seems to be the same (ref. 24 and R.G.W., results not shown). Thus the differences in filament formation between these three myosins are probably attributable to differences among the heavy chains, in agreement with our biochemical and immunological results.

Relationship to previous studies

We have demonstrated that development of rat skeletal muscle tissue is characterized by the presence of specific myosin isozymes differing from both the fast and slow adult forms. These results are consistent with several previous studies. Earlier work by Trayer and Perry¹⁰ has shown that the Ca²⁺-ATPase activity of myosin changes with development of the muscles of several animals, including rats. In addition, Drachman and Johnston⁹ have shown that actomyosin ATPase activity is low in the neonatal rat EDL (extensor digitorum longus) muscle until 5 days after birth. After this time the activity increases, reaching adult values by ~20 days. These changes in ATPase activities

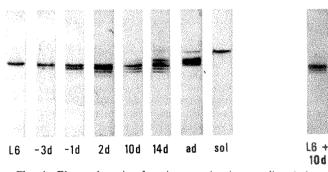

Fig. 4 Electrophoresis of native myosins in non-dissociating conditions. Myosin samples (1-3 μg) were run for 16 h at 14 V cm⁻¹ and 2 °C on cylindrical gels (5×60 mm) which consisted of 3.88% (w/v) acrylamide and 0.12% (w/v) bisacrylamide and contained 20 mM sodium pyrophosphate (pH 8.5), 10% (v/v) glycerol, 1 mM EDTA and 0.01% (v/v) 2-mercaptoethanol. Migration was from top (cathode) to bottom (anode). Abbreviations as in Fig. 1.

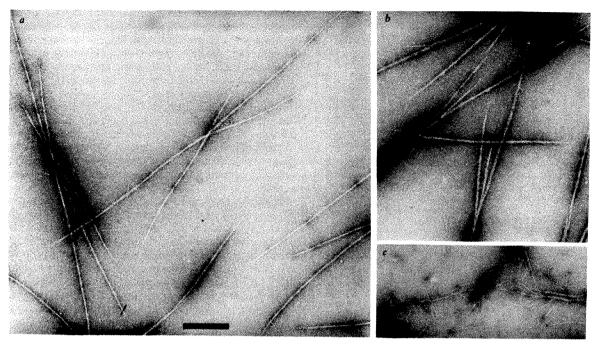

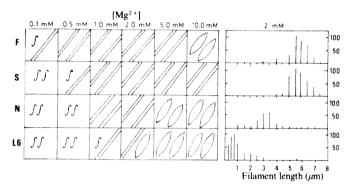

Fig. 5 Electron microscopy of synthetic myosin filaments. The upper part of the figure shows representative micrographs illustrating the overall appearance of filaments formed from neonatal myosin (10-day old muscle) in the presence of 0.1 mM ATP. The Mg²⁺ concentration in the polymerization medium was: a, 2 mM Mg²⁺; b, 10 mM Mg²⁺ and c, 0.1 mM Mg²⁺. Filaments were formed by controlled dilution and prepared for electron microscopic examination as previously described⁴⁰. The bar in a represents 0.5 μ m. The lower left part of the figure shows a schematic representation of the electron microscopic observations of the filaments formed from several types of myosins: adult fast (F), adult slow (S), neonatal (N) and embryonic myosin from fused L6 cells. Polymerization was carried out in the presence of 0.1 mM ATP and the Mg²⁺ concentration was varied over the values indicated. The parallel lines indicate the presence of long, bipolar filaments of 15-20 nm diameter (as in a; see text). The leaf-shaped

symbols indicate the presence of filaments of thicker diameter (as in b). The curved lines indicate the presence of short, branched structures (as in c). Two identical symbols in the same square indicate that the filament population was homogeneous; two different symbols indicate that the sample was apparently a mixture of filament types. The lower right part of the figure is a histogram showing the distribution of filament lengths (in μ m) observed at 2 mM Mg²⁺ for the four different myosins. In all the experiments shown here, the preparation of the myosin and the electron microscopy did not exceed 24 h to minimize any phenomena due to ageing of the myosin as noted previously⁴². A shortened protocol was therefore used to prepare the myosin. The muscle tissue was homogenized in a Polytron homogenizer in three volumes of a buffer containing 0.5 M NaCl, 0.05 M Tris-HCl (pH 6.8), 10 mM MgCl₂ and 3 mM ATP. After extraction for 20 min at 0 °C, the sample was centrifuged at 15,000g for 20 min. More ATP was added to the supernatant to give a final concentration of 6 mM, and the sample was centrifuged at 400,000g for 1 h or more to remove polymeric actin. The resultant supernatant was dialysed against a large volume of 40 mM NaCl, 30 mM Tris-HCl (pH 6.8). After ~3 h the precipitated myosin was collected by centrifugation and resuspended in 0.5 M NaCl, 20 mM Tris-HCl (pH 6.8). The myosin was stored on ice for several hours until the start of the electron microscopy experiments.

may be a manifestation of the transitions taking place among different myosin isozymes, as they occur in rats at about the same time as the observed transition from neonatal to adult myosin.

Trayer and Perry¹⁰ have also shown that changes in ATPase occur somewhat earlier in rabbit than in rat. Using polypeptide mapping, we have found that the predominant myosin heavy chain in newborn rabbits is homologous to the rat neonatal form (results not shown). Migration of the rat neonatal isozymes in native electrophoresis is also very similar to that of newborn rabbit myosin²⁵. The neonatal form of rabbit myosin persists until at least 10-15 days after birth (results not shown). This observation can be related to studies of amino acid sequence: Huszar⁴⁴ found that the myosin from 3-week old rabbits contains two different, yet homologous, histidine-containing tridecapeptides whereas adult myosin retains only one. From our results, the additional sequence found at 3 weeks post-natal probably corresponds to that of rabbit neonatal myosin and not embryonic or adult slow myosin. Both the sequence studies and the results of polypeptide mapping show that the isozyme transitions involve heavy chains that differ in primary structure. Our results are consistent with previous immunocytochemical studies on developing rat muscle 14,16 which used antibodies directed against the adult fast and slow myosins. It is likely that these antibodies cross-reacted with MHC_{emb}, MHC_{neo} or both. The use of antibodies to native myosin has demonstrated considerable antigenic homology among adult fast and slow as well as embryonic myosin heavy chains^{27,34}. Moreover the adult anti-fast myosin antibody used here (Fig. 3) clearly cross-reacts with neonatal myosin. However, it can be noted that Gauthier *et al.* 14 found that the adult pattern of antibody staining is established by the third week post-natal. This timing correlates well with the disappearance of the neonatal isozyme.

The conflicting results of immunocytochemical studies on developing chicken muscle^{13,15,19,21} may also be due to differing degrees of cross-reactivity of the antibodies with myosin types analogous to the rat embryonic and neonatal forms. It has been claimed²¹ that the myosin heavy chain of cultured chicken cells is identical to the adult protein, based on results of Ouchterlony double diffusion. It was found that if a mixture of radioactively-labelled, cultured myosin and adult fast myosin was diffused against antibodies to fast myosin then both proteins were found

Fig. 6 Schematic representation of the myosin subunits present at various times during fast muscle development. This representation is meant to illustrate concisely the predominant polypeptides present in a given situation; it does not show explicitly the stoichiometry of the native molecule nor does it indicate presumably minor combinations of heavy and light chains (such as LClemb with MHC_{neo}).

in the same precipitation line²¹. Such a result is precisely that expected if the culture myosin is different from the adult fast protein but simple shares some antigenic determinants with the latter. Polypeptide mapping studies provide evidence for a distinct developmental form of myosin heavy chain in chickens (refs 26, 45 and S.M.S. and R.G.W., unpublished observations). Thus there may be parallels between avian and mammalian muscle development concerning the myosin heavy-chain isozvmes.

Innervation and myosin isozyme transitions in muscle development

A schematic representation of the myosin transitions occurring in rat muscle development is given in Fig. 6. Our data suggest that the first heavy-chain isozyme to appear after muscle cell fusion is that designated MHC_{emb}, based on results with cultured myotubes and fetal muscle tissue^{27,46}. The light-chain subunits associated with this heavy chain evolve as cultured myotubes then mature⁴⁶. The predominant myosin heavy-chain form at different stages of development is either the embryonic or the neonatal isozyme (Fig. 6). We cannot, however, rule out the presence of small amounts of the adult fast and slow types at these stages. Immunocytochemical studies of fetal rat muscles suggest the presence of a major fibre population containing slow myosin¹⁶. Whether this result is simply due to a cross-reaction with embryonic myosin is unknown. The precise sequence of appearance of these four isozymes within individual fibres can be determined when antibodies specific to each type become available. It is possible, for example, that different fibre types evolve differently16 and that MHCemb may be a component of one type and MHC_{neo} a component of another.

Activity or trophic influences of the nerve are important in determining the phenotype of the muscle in the adult animal, and similar mechanisms might operate during development5.6 Muscle fibres of the newborn rat are in contact with several nerve axons⁴⁷. This polyneuronal innervation regresses so that by ~3 weeks after birth only one axon remains per muscle fibre. Results which suggest that both fast and slow adult myosins are present in the early developmental stages14 could be taken to indicate that a switching off of one or the other myosin type occurs in response to the establishment of the adult configuration of the neuromuscular junction. It has also been suggested 20 that only fast myosin is present in developing muscle fibres and that the induction of slow myosin can occur as a specific nerve impulse pattern is established during the regression of polyneuronal innervation.

However, our results have shown that the predominant myosin heavy-chain isozymes in developing muscle are neither adult fast myosin nor a mixture of the adult fast and slow types. One possibility is that the absence of well defined nerve activity or trophic pattern at these stages is responsible for the absence of adult myosin types. Embryonic myosin is synthesized by cultured myotubes in the absence of innervation 27,46. Whether the neonatal heavy-chain form is actively induced as a consequence of polyneuronal innervation, or whether it can be synthesized by the muscle fibre in the absence of any nervous input is unknown.

This is the first demonstration of three myosin heavy-chain isozymes occurring sequentially in fast muscle development. There have been other demonstrations of the sequential appearance of proteins of related structure and function, for example, the embryonic, fetal and adult forms of globin⁴⁸, or α -fetoprotein and serum albumin⁴⁹. The class switch of immunoglobulin molecules in the maturing lymphocyte is also an example of the sequential expression of protein isoforms. This immunoglobulin switching occurs via deletions of the DNA coding for the constant-region domains of the antibody molecule (see ref. 50). Myosin is a protein also composed of several clearly different domains1. Whether the isozymic transitions of the myosin heavy chain reported here are related to gene deletions and fusions can be tested at the protein level, by comparing the various subfragments of the different isoenzymes, and at the DNA level, using cloned gene fragments.

Distinguishing between a white dwarf and a neutron star in an X-ray binary

Joseph Patterson

Harvard-Smithsonian Center for Astrophysics, Cambridge, Massachusetts 02138, USA

It is proposed that the single most useful clue to the nature of the accreting compact star in an X-ray binary is its ratio of X-ray to visual luminosity $L_{\rm x}(2-10~{\rm keV})/L_{\star}$. Present data indicate that typical $L_{\rm x}/L_{\star}$ ratios are ~4 for white dwarfs, and ~5000 for neutron stars. These numbers are straightforward consequences of the energetics of accretion, and are approximately independent of the distance, stellar mass, and mass transfer rate. The data suggest that the ratios are also not very sensitive to any of the other system parameters, except the radius of the compact star.

Remarkably, there is still no general and reliable method for determining whether the accreting component in a galactic X-ray binary is a white dwarf or neutron star. Davidson and Ostriker¹ and Lamb et al.² argued that the pulsation periods of Cen X-3 and Her X-1 are too short to represent white dwarf pulsation or rotation periods. Lamb et al.² and Rappaport and Joss³ used the observed spin-up time scales in X-ray pulsars to establish the presence of a neutron star in most or all of these systems. Joss4 identified X-ray bursters as neutron stars, and Kylafis and Lamb⁵ suggested that all sources with $L_x >$ 5×10^{36} erg s⁻¹ contain neutron stars. None of these criteria are generally applicable, however, as most sources do not pulse, burst, or reveal their distances. The X-ray spectrum was once thought to be a useful discriminant, when the first detection of an accreting white dwarf showed a very soft spectrum⁶. But subsequent observation has shown that accreting white dwarfs are generally quite hard sources, with bremsstrahlung temperatures of ~10-30 keV (ref. 7). I propose here that the most sensitive and useful indicator of the identity of the compact star is its ratio of X-ray to visual luminosity L_x/L_y . This is easily measured; approximately independent of the distance, stellar mass and mass transfer rate; easily understood in terms of the underlying energetics of accretion; and seems to give the right answer. Figure 1 shows all available data on optically identified compact \bar{X} -ray sources. These divide neatly into two classes.

(1) The filled squares in Fig. 1 are sources discovered by scanning X-ray telescopes (hence 'X-ray selected'), and represent a nearly complete sample down to a flux level of $F_{\rm x}(2-10~{\rm keV}) \simeq 4 \times 10^{-11}~{\rm erg~cm^{-2}~s^{-1}}$. Bradt *et al.*⁸ presented data on $L_x(2-10 \text{ keV})/L_y$ for 54 sources, and seven subsequent identifications have been added: $2A0311-227 (L_x/L_v=5.5)$ (refs 9, 10), 2A0526-328 (1.6) (ref. 11), H2252-035 (3.2) (ref. 12), V1223 Sgr (2.2) (ref. 13), U Gem (1.4) (ref. 14), GK Per (5.2) (refs 15, 16) and 4U1556-60 (2,300) (ref. 17). Although Bradt et al.8 presented their data in terms of 'optical luminosity' (after applying the best available bolometric correction), we have used instead the visual flux and apply only their correction for visual absorption A_v . Thus we avoid working with large and uncertain bolometric corrections. No correction to the 2-10 keV X-ray flux is necessary, because the X-ray cutoff energies are known to be outside this bandpass. To determine the $L_{\rm x}/L_{\rm v}$ ratio of the accreting component (including an accretion disk if present), we must subtract the visual luminosity of the secondary. Where both components are visible (HZ Her, 4U2129+47, H2252-035, Cyg X-2, SS Cyg, GK Per, 2S0921-63, possibly SMC X-1), this can be done with reasonable precision; but in 23 of the 61 stars, the luminosity of the secondary is completely dominant at visual wavelengths, and hence only a lower limit to L_x/L_y can be obtained. Consequently, we exclude these 23 stars from Fig. 1. The remaining 38 stars are shown as the filled squares in Fig. 1.

The open squares in Fig. 1 are Einstein Observatory imaging

proportional counter (IPC) measurements of 25 additional optically selected cataclysmic variables, drawn from available lists (refs 7, 18, unpublished data, and P. Szkody, personal communication). We use the IPC counting rate in the 0.55-4.0 keV energy channels and the visual magnitude m_{ν} as a measure of $L_{\rm X}/L_{\rm v}$. Because eight of the X-ray-selected objects are cataclysmic variables which have been observed with the IPC, we may calibrate this ratio by requiring that the Einstein $L_{\rm X}/L_{\rm v}$ equals the ratio deduced from the data of Bradt et al.⁸. This converts roughly to: $L_x/L_y = 1$ for $m_y = 13.7$, IPC count rate = 0.22 c.p.s. (counts per s). This conversion should be fairly reliable as all these objects are nearby (~100 pc, rendering interstellar absorption unimportant), have similar UBV colours, and have similarly hard X-ray spectra. In addition to the 33 positive detections (including the eight X-ray-selected objects), there are six objects not detected, corresponding to $L_{\rm X}/L_{\rm v} < 0.1$; these are not shown in Fig. 1.

A biomodal distribution in the L_x/L_y ratios is visible in Fig. 1: the sources cluster around mean values of $L_x/L_y = 4$ and 4,900. Because there are two known stable configurations for compact stars with radii differing by a factor of $\sim 10^3$, the neutron-star and white-dwarf population of the two classes should be investigated. The existence of neutron stars in systems containing X-ray pulsars with short spin-up times, and neutron stars or black holes in systems containing X-ray bursters or with $L_x >$ 5×10^{36} erg s⁻¹ can be certified, as can the existence of white dwarfs in classical novae, dwarf novae, AM Herculis stars, and X-ray pulsars with long spin-up times. To avoid optical selection effects only X-ray selected objects are considered. All certified white dwarfs and neutron stars are labelled W or N respectively in Fig. 1. In the group near $L_{\rm X}/L_{\rm v}=5{,}000$, we find 12 neutron stars, no white dwarfs, and 17 uncertain cases. In the group near $L_{\rm X}/L_{\rm v}=4$, we find no neutron stars, seven white dwarfs, and two uncertain cases. The natural inference is that accreting neutron stars typically have $L_x/L_v \sim 5{,}000$, white dwarfs typically have $L_{\rm X}/L_{\rm v}$ -4, and the lack of overlap between the two classes emphasizes the value of $L_{\rm X}/L_{\rm v}$ as a signature of the presence of a white dwarf or neutron star. The Einstein observations of cataclysmic variables (which are known to contain white dwarfs) confirm that our nine objects near $L_x/L_v = 4$ are not aberrant cases, but are fairly typical of accreting white dwarfs (with high $L_{\rm X}/L_{\rm v}$ objects preferentially detected in X-ray surveys, as would be expected).

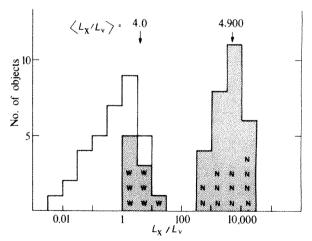

Fig. 1 Distribution of $L_{\rm X}/L_{\rm v}$ ratios for the accreting component of optically identified compact X-ray sources. \square , Sources identified from scanning X-ray telescopes; \square , Einstein observations of optically selected cataclysmic variables (the X-ray and optical measurements during quiescence were used for dwarf novae). The average values of $L_{\rm X}/L_{\rm v}$ are indicated for the group near $L_{\rm X}/L_{\rm v}=1$ and = 5,000. Systems known to contain white dwarfs and neutron stars are labelled W and N respectively.

This result is easy to understand in terms of the energetics of disk accretion, as most of the optical light emerges from large radii in the disk (where there is no dependence on the nature of the compact star), but the X rays emerge from gravitational potential wells which differ in depth by a factor of $\sim 1,000$. For a self-luminous steady-state accretion disk19 surrounding a 1 Mo neutron star, (or black hole, which is for present purposes equivalent to a neutron star), with $\dot{M} = 10^{-10} M_{\odot} \text{ yr}^{-1}$, only 5% of the optical luminosity is produced at radii less than a typical white dwarf radius of 6×108 cm. Thus, for accretion rates near $10^{-10} M_{\odot} \text{ yr}^{-1}$, we have approximately

$$L_{\rm v} = 3 \times 10^{32} \,{\rm erg \, s^{-1}} \left(\frac{M_{*}}{1M_{\odot}}\right) \left(\frac{\dot{M}}{10^{-10} M_{\odot} \,{\rm yr^{-1}}}\right)$$
 (1)

independent of the nature of the compact star. But the bolometric luminosity (L_{bol}) depends on the radius R_* of the compact star:

$$L_{\text{boi}} = 3 \times 10^{33} \text{ erg s}^{-1} \left(\frac{\dot{M}_{*}}{1M_{\odot}} \right) \left(\frac{\dot{M}}{10^{-10} M_{\odot} \text{ yr}^{-1}} \right) \left(\frac{R_{*}}{6 \times 10^{8} \text{ cm}} \right)^{-1} (2)$$

If a fraction k of the accretion energy emerges in hard X rays, then $L_x = kL_{bol}$, and therefore

$$L_{\rm x}/L_{\rm v} = 10 \ k \left(\frac{R_{*}}{6 \times 10^8 \ {\rm cm}}\right)^{-1}$$
 (3)

Now for both neutron stars and white dwarfs, the observed bremsstrahlung temperatures are in the range 10-30 keV, hence our adopted 2-10 keV window will typically miss ~50% of the X-ray flux. For white dwarfs, a well-formed accretion disk may radiate at optical and UV wavelengths much of the total gravitational energy available, lowering the value of k still further. Reasonable values are therefore k = 0.5 for a neutron star and k = 0.2 for a white dwarf. Then the expected values of $L_{\rm X}/L_{\rm y}$ become 2 and 3,000 for white dwarfs and neutron stars respectively.

Refinements to this plausibility argument—especially the consideration of detailed emission mechanisms—will be worth adding in the future. Two of the stars in the X-ray-selected sample are AM Her stars, in which accretion is thought to proceed by radial infall onto the white dwarf, without the mediation of an accretion disk. Yet their L_x/L_y ratios are typical of the entire class of accreting white dwarfs (4.0 for AM Her, 5.5 for 2A0311-227). Similarly, some fraction of the accreting neutron stars may produce most of their visual luminosity by reprocessing X- rays in the disk, which ought to lower the $L_{\rm X}/L_{\rm v}$ ratio from that expected in a pure accretion model. However, there is no obvious signature of the reprocessors in Fig. 1. We can speculate that the AM Her stars will be found to inhabit the high end of the $L_{\rm X}/L_{\rm v}$ distribution for accreting white dwarfs, and the reprocessors will prefer the low end of the $L_{\rm X}/L_{\rm v}$ distribution for accreting neutron stars. Good candidates for the latter include A0620-00, 2S0921-63, HZ Her, 4U1626-67, 4U1659-49, 4U1822-37, Aql X-1, and 4U1957+11. But the data do not yet demand this segregation. Presumably, the great difference in the depths of white dwarf and neutron star gravitational potential wells overpowers effects arising from the local geometry and the detailed emission mechanisms. Because $L_{\rm X}/L_{\rm v}$ is simple to measure and depends strongly only on the radius of the compact star, it seems to be the most useful and reliable indicator of the nature of the compact star.

How will discarding our selection criteria affect Fig. 1? The Einstein observations of cataclysmic variables show that the mean value of L_x/L_y for white dwarfs will decrease to ~ 1 . The mean value for neutron stars will probably increase, as there are many unidentified sources with small error boxes containing only very faint stars (whereas X-ray sources with bright counterparts have probably not been missed). In addition, our deduced values of $L_{\rm X}/L_{\rm v}$ must be increased if a significant fraction of the optical light is produced by means other than accretion—a very real possibility for neutron-star sources. Thus it seems likely that the empirical gulf between white dwarfs and

neutron stars in Fig. 1 will remain sufficiently wide to provide an unambiguous discriminant.

The use of the L_x/L_y discriminant should help to classify newly discovered X-ray binaries. Among presently known sources, there are controversies concerning the nature of the compact star in Sco X-1 ($L_{\rm X}/L_{\rm v} = 5{,}000$) (ref. 20), Cyg X-2 (11,000) (ref. 20), 4U1822-37 (300) (ref. 21), 4U2129+47(1,900) (ref. 22), and H2252 – 035 (3.2) (refs 23, 24). According to our criterion, the first four should be classified as neutron stars, and the last as a white dwarf. Of course, our criterion does not distinguish neutron stars from black holes. Finally, it should be emphasized that 38% of the identified sources have not been considered, in which the existence of a luminous secondary prevents the use of the L_x/L_y discriminant.

Pulsar slow-down epochs

H. Heintzmann

Institut für theoretische Physik der Universität zu Köln, 5000 Köln 41, FRG

Theoretical arguments about the progenitors of pulsars suggest that all neutron stars may have essentially the same mass¹ and the same magnetic moment^{3,4} M. Direct determinations^{5,6} support this view and give $m \approx 10^{33.5}$ g (the Chandrasekhar mass) and $\vec{M} \simeq 10^{30.5}$ G cm³ and theoretically inferred values for accreting binary systems^{7,1} show a surprisingly small scatter. Can this apparent uniformity of binary pulsars be reconciled with the timing data for (single) radio pulsars, many of which may have also been binaries for some time? In most theories it is assumed that the neutron star is slowed-down by the combined action of a plasma-current torque and a vacuum-wave torque. This has led to the conclusion that there is a deficiency in 'old' pulsars (as measured by their 'slow-down age' P/P) and that the inferred magnetic moments vary by two orders of magnitude. A worse result is the derived pulsar birth rate² of one per 10 yr if the half life of a pulsar is 106 yr as follows from the standard slow-down theory. From these facts we present a new model for pulsar slow-down. The present model predicts four different slow-down epochs from evolutionary changes of the magnetosphere, which are dominated by different braking mechanisms. The model assumes that the masses, magnetic moments and initial rotation periods of all neutron stars are equal. We show that no direct relationship can exist between the 'slow-down age' and the true age of a pulsar and that the pulsar birth rate is one per 100 yr.

Although radio pulsars have been identified with rotating, magnetized neutron stars8 and it has been shown that they must be surrounded by a magnetosphere 9,10 which is independent of the neutron star's surface 11,12 the progress towards understand-

ing the aspects of the magnetosphere, which determine the slowing-down ('braking') of the neutron star's rotation, has been slow¹³. The theoretical analysis of pulsar braking is hampered by two facts: no self-consistent solution for a pulsar magnetosphere has been found and that the pulsar timing data seem to reveal more about the neutron star's interior 14 than about its magnetosphere. The profusion of radio observations can at best be used as a diagnostic13 for the slow-down process. The present model is based on the following assumptions. (1) 'Young' pulsars produce so much plasma by means of 'sparking' 11,12 that within the plasma no low-frequency wave can propagate 15,16. (2) As pulsars 'grow older' sparking becomes less effective so that low-frequency waves can eventually be emitted from within the plasma. (3) The Goldreich-Julian model as extended to the oblique rotator by Mestel describes the long-term aspects of the magnetosphere out to the velocity-of-light cylinder (that part of the magnetosphere which, were it to corotate rigidly. would rotate at the speed of light). Minor modifications such as a current-regulating net charge and discharges due to radiation friction will be worked into the model later. (4) Considerable counteralignment between magnetic moment and the spin of the neutron star occurs during the first epoch, where the torque is dominated by currents in the plasma (the term 'counteralignment' is used here in the sense of perpendicularity it does not mean magnetic moment and angular momentum becoming antiparallel). The present model accounts for this counteralignment if the star can be treated as a sphere so that free nutation is not possible 17,18. However, any other (internal) mechanism which leads to considerable counteralignment will lead to the same consequences (see ref. 18 and refs therein).

The Goldreich-Julian model of the pulsar magnetosphere predicts an excess charge-density in the magnetosphere

$$q \simeq -\frac{\vec{\Omega} \cdot \vec{\mathbf{B}}}{2\pi c} \tag{1}$$

and an average current

$$\vec{\mathbf{j}} \simeq qc\,\vec{\mathbf{b}}_0 \tag{2}$$

along the open field lines which flow away from the surface area ΔF centred on the magnetic poles (polar caps). Here $\vec{\Omega}$ is the spin angular velocity, \mathbf{B} the magnetic field, c the velocity of light and \mathbf{b}_0 a unit vector in the direction of \mathbf{B} . For the star not to charge up indefinitely there must be a back-current which flows along magnetic field lines further away from the centre of the polar cap: it will be regulated by a net charge. To close the current, charges must flow within the neutron star across the magnetic field lines and it is this current which breaks the neutron star's rotation. In the Goldreich-Julian model it is assumed that energy and angular momentum are dissipated beyond the velocity-of-light cylinder. Within the velocity-oflight cylinder the charges move along the magnetic field lines like beads on a wire and their current provides a 'magnetic spring' between the neutron star's surface and the matter beyond the velocity-of-light cylinder. Its torque \vec{T} is given by

$$\vec{\mathbf{T}} = \frac{1}{4\pi r} \int (\vec{\mathbf{r}} \cdot \vec{\mathbf{B}}) \vec{\mathbf{r}} \times \vec{\mathbf{B}} \, dF$$
 (3)

where \vec{r} is the radius vector counted from the centre of the star and the integral is taken over a sphere of radius r. The current of equation (2)—in fact any current along the magnetic field lines which brakes the rotation—leads to a counteralignment torque ¹⁸ between $\vec{\Omega}$ and \vec{M} , in distinction to the torque exerted

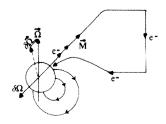

Fig. 1 Schematic current flow which leads to counteralignment. If $\vec{\Omega}$ and \vec{M} are parallel the current flow is metastable. The electron-flow is shown, the algebraic current \vec{j} is directed oppositely. The currents have axial symmetry about the dipole direction \vec{M} .

by low-frequency waves propagating in vacuo, which (if not impeded by nutation¹⁷) leads to alignment 19,20 . The counteralignment torque can be easily understood by noting that a current flowing through a magnetized sphere will set the sphere into rotation about the magnetic dipole axis $\tilde{\mathbf{M}}$ and the current of equation (2) is directed (Lenz' rule) so that it reduces the rotation about the original axis.

In the dipole approximation the polar cap surface area ΔF is given by $^{9,11}\Delta F\simeq 2\pi R^2$ ($\Omega R/c$), where $R\simeq 10^6$ cm is the radius of the star and in a coordinate system centred on the magnetic dipole-axis we find for the toroidal component of the magnetic field

$$B_{\phi} \simeq -\frac{\vec{\Omega} \cdot \vec{B}}{2\pi c} \cdot \int \frac{\mathrm{d}F}{R \sin \theta} \tag{4}$$

which leads by means of equation (3) to a torque

$$\vec{\mathbf{T}}_{pl} = -\alpha \frac{\Omega^2}{c^3} (\vec{\mathbf{\Omega}} \cdot \vec{\mathbf{M}}) \vec{\mathbf{M}}$$
 (5)

where $\vec{M} = R^3 \vec{B}$ is the magnetic dipole moment and $\alpha = 1$. From the corotating part of the magnetosphere we obtain an induced magnetic field parallel to the rotation axis which leads to an extra torque (by means of the magnetic dipole moment \vec{M}) on the star

$$T'_{pl} = \frac{\gamma}{Rc^2} (\vec{\Omega} \cdot \vec{M}) \vec{\Omega} \times \vec{M}$$
 (6)

where $\gamma \approx 1$. Equations (5) and (6) may be compared with the vacuum-wave torque 17,19,20

$$\vec{\mathbf{T}}_{w} = -\beta \frac{\Omega^{2}}{c^{3}} (\vec{\mathbf{M}} \times \vec{\Omega}) \times \vec{\mathbf{M}} + \frac{1}{Rc^{2}} (\vec{\mathbf{M}} \cdot \vec{\Omega}) \vec{\Omega} \times \vec{\mathbf{M}}$$
(7)

with $\beta = 2/3$. The common assumption that both plasma and low-frequency waves will contribute (more or less equally) to the slow-down torque, which leads to the large scatter in inferred magnetic dipole moments will now be shown to be wrong. If low-frequency waves cannot propagate within the plasma they cannot exist outside. Apart from a transition period where the plasma may just allow for low frequency wave propagation (the duration of which is difficult to estimate as it depends on the sparking mechanism) a pulsar is slowed-down therefore exclusively by either the plasma-current torque equation (5) or the vacuum torque equation (7).

The orthogonal rotator provides the most favourable conditions for low-frequency wave-emission and we assume that the plasma which flows out of the velocity-of-light cylinder fills the space about the equatorial plane, consequently the waves are emitted into a plasma dead zone centred on the rotations axis. Let us assume that the two zones are separated by a cone of half-angle ψ (counted from the rotation axis) and as a first approximation ¹⁶ that the plasma is infinitely well conducting.

This problem can be solved exactly. Taking the solution of the vector-Helmholtz equation from Morse and Feshbach²³ one finds that the TEM-mode dominates and the dominant radiation mode is given by the lowest n for which

$$\frac{n+1}{n}P_{n-1}^{1}(\cos\psi) - \frac{n}{n+1}P_{n+1}^{1}(\cos\psi) = 0$$
 (8)

$$P_n^1(\cos\psi) = \frac{n(n+1)}{2}\sin\psi F\left(1-n, 2+n|2|\frac{1-\cos\psi}{2}\right) \quad (9)$$

F in equation (9) is the hypergeometric function which for non-integer n is regular in the upper hemisphere where equations (8) and (9) hold. If we let the conducting cone shrink to the equatorial plane one obtains the Deutsch solution²⁴ with n = 1. For a thin plasma sheet $(\psi = \pi/2 - \varepsilon)$ one finds approximately

$$12 = (1 - \cos \psi) \cdot (n^2(n+2)(n+3) - (1-n^2)(1+n)(2-n)) \quad (10)$$

which shows that n is > 1. The radiated energy rate is

$$\dot{E} \simeq -\frac{2}{2cR^2} (\vec{\mathbf{M}} \times \vec{\mathbf{\Omega}})^2 \left(\frac{\Omega R}{c}\right)^{2n} \tag{11}$$

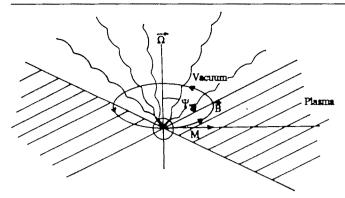

Fig. 2 Plasma-vacuum configuration for which an exact solution of the vector—Helmholtz equation is possible. Hatching indicates the area supposed to be filled with overdense outstreaming plasma in which no low-frequency waves can propagate. Equation (11) gives the energy-loss due to low-frequency waves radiated into vacuum and n is determined from equations (8) or (10)

For a finite thickness of the plasma sheet the emission of low-frequency waves is so strongly reduced $(n=2 \text{ for } \psi=\pi/4)$ that the wave pressure cannot balance the plasma pressure at the boundary and the plasma fills the whole space. Note, however, that if the plasma is asymmetrically distributed in the two hemispheres, such that one cone has $\psi > \pi/2$ (plasma swept backwards, for example, by the pulsar's proper motion?¹⁵) radiation emission is enhanced and such a state may be called superradiant. A young pulsar will therefore be slowed-down exclusively by the plasma current, an old one by the wave-torque and in the transition epoch we may have

$$\dot{\vec{\mathbf{J}}} = I \dot{\vec{\mathbf{\Omega}}} = (\beta - \alpha) \frac{\Omega^2}{c^3} (\vec{\mathbf{M}} \vec{\mathbf{\Omega}}) \vec{\mathbf{M}} - \beta \frac{\Omega^2}{c^3} \mathbf{M}^2 \vec{\mathbf{\Omega}} + \gamma \frac{(\vec{\mathbf{\Omega}} \vec{\mathbf{M}})}{Rc^2} \vec{\mathbf{\Omega}} \times \vec{\mathbf{M}}$$
(12)

where \vec{J} is the angular momentum and I the moment of inertia of the neutron star, $I \simeq 10^{45}$ g cm².

Together with the equation of motion for the dipole moment \vec{M} , which is frozen into the star

$$\vec{\mathbf{M}} = \vec{\mathbf{\Omega}} \times \vec{\mathbf{M}} \tag{13}$$

the evolution of the slow-down is easy to determine. Note that equation (12) takes into account only the convection current of equation (2). An additional conduction current due to sparking which may be larger than the convection current will only lead to a different α if the current flows along the magnetic field lines as depicted in Fig. 1. None of the conclusions regarding the first slow-down epoch will be affected as long as $\beta = 0$ as can be seen from equation (14) which becomes independent on α in this case. With the help of the first integral

$$\frac{(\Omega^2 \sin^2 \chi)^{\alpha}}{(\Omega^2 \cos^2 \chi)^{\beta}} = \text{constant}$$
 (14)

where χ is the angle between $\vec{\Omega}$ and \vec{M} we obtain for young pulsars, for which $\beta = 0$,

$$\sin \chi = \sin \chi_1 \left(\frac{\Omega_1}{\Omega}\right) \tag{15}$$

$$\Omega = \Omega_{1}(1 + ctg^{2}\chi_{1}(1 - e^{-\tau}))^{-1/2}$$
(16)

which for small times

$$\Omega = \Omega_i \left(1 - \frac{\tau}{2} ctg^2 \chi_i + \frac{\tau^2}{8} \left(2ctg^2 \chi_i + 3ctg^4 \chi_i \right) \right)$$
 (17)

where $\tau = 2\alpha \Omega_1^2 \sin^2 \chi_1 (M^2/Ic^3)t = t/t_0$ is a dimensionless parameter which measures the observer's time t in units of the e-folding time t_0 of the model, i refers to initial values.

Before discussing equation (16), we will consider briefly another important parameter for pulsar timing observations. The so-called braking index $N = (\Omega\Omega/\Omega^2)$ is given in our model by

$$N = 3 + 2 \frac{(\beta - \alpha)^2 \cos^2 \chi \sin^2 \chi}{(\alpha \cos^2 \chi + \beta \sin^2 \chi)^2}$$
 (18)

and is never < 3 due to torque minimization. Observationally N is reliably known only for the Crab pulsar^{26,27} where $N \simeq 2$, 5. Rewriting the energy balance equation in the form

$$\frac{1}{2}(I\Omega^2) = -\frac{\alpha}{cR^2}(\vec{\Omega}\vec{\mathbf{M}})^2 \left(\frac{\Delta F}{F}\right)^2$$
 (19)

where $F=4\pi R^2$ is the surface area of the neutron star. A braking index of <3 may be explained by the pulsar's crust shrinking^{21,22,28} at a rather large rate, or by a slightly larger polar cap $\Delta F/F=(\Omega R/c)^{2/3}$. In fact, some theories²⁹ have the pulse width ΔP and the period P related as $(\Delta P/P)^2=\Delta F/F$ and the observations of the Crab pulsar, where $\Delta P/P\sim 1/5$ is rather large²⁹, would fit better with $\Delta F/F\simeq (\Omega R/c)^{1/2}$ leading to a braking index $N=3-2/3+2tg^2\chi$.

The model is flexible enough to account for the available timing data even under the restriction that all pulsars have the same moment of inertia $I=10^{45}\,\mathrm{g}\,\mathrm{cm}^2$ and the same magnetic moment $M=10^{30.5}\,\mathrm{G}\,\mathrm{cm}^3$. To determine t_{\bullet} from the observations we identify those pulsars with anomalously low period derivative with the stars in our model which pass through the end of the first epoch. From the observations $\Omega \simeq 2\pi\,\mathrm{s}^{-1}$ which gives $\Omega_{\bullet} \sin \chi_{\bullet} = 2\pi\,\mathrm{s}^{-1}$ so that

$$t_{\bullet} \simeq 10^6 \text{ yr } I_{45} M_{30.5}^{-1}$$
 (20)

Observationally the two most extreme cases are the Crab pulsar and the binary pulsar. For them equation (20) would lead to $\sin \chi_1 = 10^{-1.5}$ and $\cos \chi_1 = 10^{-1.5}$ respectively if we assume that both are young objects. To explain the binary pulsar in this way a nearly orthogonal rotator is needed and one may worry whether equation (12) still applies. This case requires $\beta < 10^{-4}$ and $\cos^2 \chi_1 < 10^{-3}$. For the binary pulsar $(\Omega R/c)^2 < 10^{-5}$, which guarantees that $\beta < 10^{-4}$ and inspection of the current given by equation (2) shows that it can be closed along the magnetic field lines through the star so that it does not lead to a torque. The braking is then no longer effected by the current of equation (2) but comes about through secondary energy losses such as sparking. Ruderman's estimate12 of that energy for the (faster) Crab pulsar of 10³³-10³⁴ ergs s⁻¹ would lead to the observed braking of the binary pulsar. The first epoch, which lasts some 106 yr accounts for roughly a half of the pulsars assuming that all are born as fast rotators. The other half can be explained in the penultimate epoch of pulsar slow-down, where vacuum waves can be emitted in the presence of plasma so that the period derivative goes back to its normal value. Note that in the present model the slow-down age is not related to the true age. The mean active life as determined by Ohmic dissipation can easily exceed 107 yr (ref. 18) which brings down the pulsar birth rate by a factor of 10, in comfortable agreement with the more conservative estimates of supernova rates and the lack of discovered neutron stars at their centres36

We have so far only assumed that the current of equation (2) flows on average without demonstrating how it occurs. Of course, a rigorous demonstration requires a self-consistent solution of the magnetosphere problem, so only the following qualitative argument can be given. According to the Goldreich-Julian model particles cannot stay on open field lines within the velocity of the light cylinder for the same reason that they cannot stay within the star: large electric fields would pull them out. This causes the charge with the correct sign as given by equation (1) to be pulled out, charges with the opposite sign, however, are pulled in on the same field line. Hence a pulsar must have a net charge 30 Q to regulate the plasma outflow such that the star does not charge up indefinitely. Some of the charge will be distributed over the polar cap ΔF and most of it over the boundary of the corotating magnetosphere and because it must be able to influence the dynamics of the plasma at the velocity-of-light cylinder it must be of the order of

$$Q \simeq \frac{\vec{\Omega} \vec{M}}{c} \tag{21}$$

Such a charge reintroduces large electric fields parallel to B, so we have shifted the whole problem from the surface of the neutron star to its velocity-of-light cylinder, sufficiently far away, however, that the star does not get too heated 1,36. Note that the net charge as given by equation (21) will not give rise to a back current from the interstellar matter to the pulsar during its active life. This is because the pulsar is well shielded by the electromagnetic fields of the magnetosphere or the vacuum waves which both fall off like r^{-1} whereas the monopole field falls off like r^{-2} so that the force balance is in fact at the velocity-of-light cylinder. It follows that the exact current need not be that given by equation (2) but may be determined by the global magnetospheric structure. As pointed out by Mestel (personal communication) this need not have the symmetry about \vec{M} , which was crucial for deriving equation (5). In the general case one cannot therefore rigorously predict whether there will be counteralignment or alignment, whereas vacuum waves will always lead to alignment.

In the penultimate slow-down era, which is dominated by low-frequency waves this charge and the corotating (quadrupole) charge of the magnetosphere will also radiate leading to a friction force on the particles in the magnetic field with nonvanishing curl. To compensate for this, the particles must drift across magnetic field lines producing a current which empties the magnetosphere. For the quadrupole radiation from the corotating magnetosphere we get for the time scale of the ensuing discharges some 106 pulsar periods and a much shorter time scale for the dipole radiation due to the charge given by equation (21). These discharges may be related to the nulling phenomenon and may give rise to slow-down noise 27,28 but not to any directly observable speed ups as the inertia involved is too small. The present model does not explain why pulsars turn off unless sparking ceases to be regular enough to allow an observer to detect the object as a pulsar, but even accretion may apparently influence the final era31 especially if the pulsar has become an aligned rotator by then.

An attractive explanation is obtained, however, by combining the pulsar extinction hypothesis^{32,33} with the decay of the magnetic dipole moment is which regulates the physics at the velocity-of-light cylinder. The observed cutoff period $P \simeq 4 \text{ s}$ would then not mainly be a consequence of plasma inertia but rather reflect the time scale for ohmic dissipation in the pulsar's crust which may vary considerably from pulsar to pulsar depending on its thermal history at birth. According to the present model such neutron stars will slow-down in the final era by quadrupole radiation (or plasma currents) on a time scale exceeding the age of the Universe and only if they traverse dense interstellar matter may they be slowed-down more effectively by accretion³¹. The γ -ray transient³⁴ with a period of 8 s could in fact be such an old pulsar, whereas the γ -ray source CG195,5+ 4,5, if its periodicity of 59.35 s should be confirmed³⁵, should rather not be identified with an old pulsar according to the present model, which predicts ultimate periods around 10 s for dead pulsars, instead of 60 s as deduced by Michel³² assuming that the dipole field does not decay.

The final version of this paper was written at the Centro Brasileiro de Pesquisas Físicas, Rio de Janeiro, and I thank the CNPq for financial support, Professor Novello for hospitality and especially T. Gold for helpful discussion.

IR photometry of flat spectrum radio sources

C. D. Impey & P. W. J. L. Brand

Department of Astronomy, University of Edinburgh, Royal Observatory, Edinburgh EH9 2HJ, UK

IR measurements of optically faint, flat spectrum radio sources have implied the possible existence of a new class of quasar, with IR excess more extreme than that of any extragalactic object. In the present preliminary study, 18 Parkes flat spectrum sources have been observed in the IR without regard to optical morphology, and the red sources are found to be just the tail of the normal distribution of quasar colours. The results imply that a considerable fraction of flat spectrum sources from complete samples may have properties similar to the BL Lac objects.

Rieke et al.^{1,2} recently detected several objects at 2.2 µm in optically blank fields of flat spectrum radio sources^{3,4}, and derived such large IR/optical spectral indices ($\alpha = -d \ln flux$ density/d ln frequency) $\alpha_{KB} \approx 3$ that they proposed a new class of quasar, because other properties of the objects indicated that they were similar to violently variable quasars, or BL Lac objects. They further noted that at the largest (faintest) blue magnitudes, α_{KB} tended to be high, while at $m_B \le 18$, $\alpha_{KB} \approx 1$, a value typical for the optically bright quasars of Neugebauer et al^5 . The spectral index α_{KB} was calculated from measurements in the optical B band and the near-IR K band. To test the trend of α with $m_{\rm B}$, and to discover whether the red sources represent a new class of quasar, a sample of flat spectrum radio sources was observed in the IR without regard to optical identification. The candidates were selected from the list of 2.7-GHz sources of Condon et al.³ according to limits on spectral index (α < 0.5, 2.7 – 5.0 GHz), flux density ($S_{2.7} > 0.5$ Jy), RA (8 h < α < 15 h) and dec $(-30^{\circ} < \delta < -4^{\circ})$.

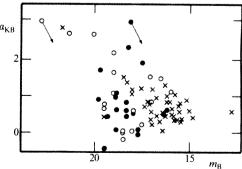

Fig. 1 Optical/IR spectral index versus optical magnitude, showing Rieke et al.'s objects $^{1.2}$ (\bigcirc), the optically bright quasars of Neugebauer et al. 5 (\times) and objects from the present study (\blacksquare). Trajectories show the effect of 1 mag brightening at B between epoch of Palomar plates and IR measurements.

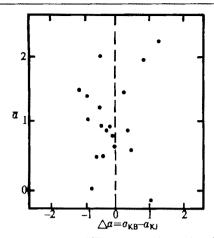

Fig. 2 Plot of mean optical/IR spectral index against the residual $\alpha_{KB} - \alpha_{KI}$. The deviation from the line $\alpha_{KB} = \alpha_{KI}$ is a measure of the curvature of the spectrum (either intrinsic or due to variability).

The IR observations were obtained with the Anglo-Australian 3.9-m telescope on 2-3 May 1980 using the InSb Infrared Photometry System. All the observations were made with the broad band $K(2.2 \,\mu\text{m})$ and $J(1.25 \,\mu\text{m})$ filters. Standard stars from the AAO list were observed to calibrate the photometry. The data have been corrected for near-IR extinction at Siding Spring according to recently determined coefficients (G. Gilmore and I. N. Read, personal communication). The data have also been corrected for the effect of different flux distributions on the broad band flux measurements. Only two of the sources lie at galactic latitude $|b| < 30^\circ$, and they were corrected for galactic extinction. The minimum error in the J and K magnitudes was determined from the repeatability of standard observations during a night. In two nights, 21 sources were observed, with 20 detected at K and 18 detected at J.

Table 1 shows the IR data, along with spectral indices calculated between J and K (α_{KJ}) and between the optical B band and K(α_{KB}). There are two major sources of error in these spectral indices; one is the effect of redshifted emission lines passing through the photometric bands. α_{KJ} may be affected, but over the long baseline from 2.2 μ m to the visible, α_{KB} is relatively insensitive to this effect⁶. The second is the fact that the optical magnitude is taken from Palomar plates, and variability might lead to errors in α_{KB} . The photographic fluxes have an uncertainty of ± 0.5 mag (ref. 3).

Figure 1 shows α_{KB} plotted against m_B , with the cluster of red, optically faint objects showing up clearly in the previous data. The 18 sources in our sample present a distribution of spectral indices covering the full range of α from 0 to 3. Very red sources are relatively common; four out of 18 lie in the top part of the

range of spectral indices for BL Lac objects and two are as red as any of those found by Rieke and Lebofsky¹. The data fill in the distribution of very red objects at brighter optical magnitudes, and shows that the trend of α_{KB} with m_B is a selection effect.

Figure 1 shows that much of the argument rests on the α_{KB} indices of the two reddest objects (1335-127 and 1034-293), which may be affected by variability. However, there are reasons to believe that these points are not spurious. First, direct observations on the AAT TV acquisition system confirmed that neither of the objects had varied by more than a magnitude from the epoch of the Palomar plates. The effect of 1 mag variability in B is shown as a trajectory in Fig. 1 both for 1335-127 from the present study and for the reddest object from refs 1, 2. While anomalous brightness at B would bring the two red objects down towards the bulk of the distribution, the same is true of the original red objects. As both sets of α_{KB} were calculated in the same way, the results are directly comparable. Second, there is no evidence from the cotemporaneous J and K measurements that these objects are abnormal. Figure 2 shows the mean spectral slope $\bar{\alpha}$ plotted against the difference $(\alpha_{KB} - \alpha_{KJ})$, where the steep spectrum sources lie at the top of the graph. Rieke et al. 1.2 noted that a roughly constant spectral index satisfied both their J, K and optical fluxes; this is represented by the line $\alpha_{KB} = \alpha_{KI}$ in Fig. 2. Figure 2 also shows that the objects with large α_{KB} do not have abnormally large residuals $\Delta \alpha$, and are not

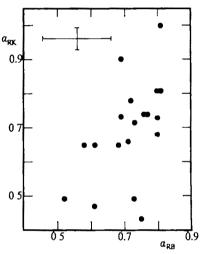

Fig. 3 Plot of radio/IR and radio/optical spectral indices. The dispersions in α_{RR} and α_{RB} are a measure of the relative IR and optical flux variations of the sample. Typical error bars are shown in the top left corner.

segregated from the main body of the distribution. While there is not a 1:1 correspondence between steep α_{KB} and steep α_{KJ} , the four reddest objects in α_{KB} are among the eight reddest objects in α_{XI} . The means and dispersions of both spectral index distributions are similar $(\bar{\alpha}_{JK} = 1.05 \pm 0.72, \ \bar{\alpha}_{KB} = 0.92 \pm 0.79)$. There is no evidence from either the optical or IR data that the red (α_{KB}) objects are other than the tail of the normal distribution of quasar colours. Objects which resemble BL Lac objects in their IR properties are relatively common. The four reddest sources are particularly interesting because (unlike the original 'red' sources) they are bright enough for follow-up spectroscopy and polarimetry. The reddest object (1335-127) has recently been confirmed as a BL Lac object. Our 2.2-um measurements with the UK Infrared Telescope show it to have varied by a magnitude over one year, and radio observations by Aller et al. show it to have variable linear polarization at frequencies from 4.8 to 14.5 GHz. In addition, the second reddest object (1034-293) shows evidence of variability $(\Delta m_{\rm B} > 1 \text{ mag})$ from UK Schmidt plates of the area, another indication that it is a BL Lac-type object.

Even for this relatively small sample it is possible to draw conclusions on the IR properties of flat spectrum radio sources,

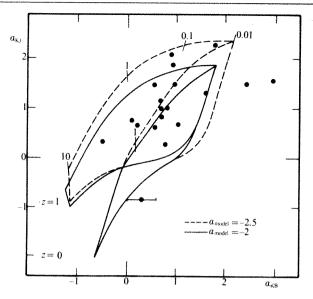

Fig. 4 Plot of near IR and optical/IR spectral indices with permitted zones from a two-component model. The error bars on the lowest point show the effect of a variation of $\pm \frac{1}{2}$ mag in B and typical 5% precision on the J and K flux measurements.

and compare them with the optical properties. Selection effects will not be important because the radio sample was completely identified optically, and with one exception was completely identified at 2.2 μ m. Figure 3 shows α_{RK} plotted against α_{RB} , where the spectral index is calculated between the 2.7 GHz measurement and the K and B data points. The range of radio fluxes is less than a factor of 3, while the range of IR fluxes is >500, thus the graph allows a comparison of the range of IR and optical fluxes in the sample. The mean spectral indices are $\bar{\alpha}_{RK} = 0.69$ and $\bar{\alpha}_{RB} = 0.71$, both very near to the canonical value for optically thin non-thermal radio sources. There is no significant difference between the range of IR and optical fluxes $(\sigma(\alpha_{RK}) = 0.15, \ \sigma(\alpha_{RB}) = 0.08$ and taking the relative standard error in the variance of n variates to be $1.4 (n-1)^{-1/2}$) and the even distribution of the very red objects on the α_{RB} axis is a confirmation of the fact that they do not tend to be optically faint. The objects of Rieke et al.² do not come from a separate population at better than the 1.5σ level; removing the lower four objects only reduces $\sigma(\alpha_{RK})$ by 0.03 to 0.12.

To see if a simple picture accounts for the range of optical/IR spectra, the energy distribution of a giant elliptical8 was added to a power law spectrum of slope α which flattened off $(\alpha = 0)$ at some wavelength λ_n (the knee). Figure 4 shows the data plotted on a two-colour diagram of α_{KB}/α_{KJ} . The extreme red objects lie at large values of α_{KB} . As the knee wavelength travels across the spectrum, the source traces a trajectory in the two-colour plane. As the proportion of non-thermal to thermal components is varied, the trajectory sweeps out an area on the diagram. The right-hand boundary represents the extreme non-thermal case of $S_{GAL}/S_{NT} = 0.01$, where S_{GAL} is the peak flux of the elliptical galaxy and $S_{\rm NT}$ is the flux at the point where the power law flattens. As the flux contribution of the elliptical increases, the trajectory sweeps across to smaller values of α_{KB} and α_{KJ} , and the left-hand boundary of the enclosed area shows the case where $S_{GAL}/S_{NT} = 10$ and the spectrum is dominated by stellar flux. The redshift distribution of flat spectrum radio samples is expected to peak around $z \sim 1$ (ref. 9), and Fig. 4 shows the case for z = 0 and z = 1. Given the luminosity of a giant elliptical, the flat spectrum sources would be expected to populate the nonthermal $(S_{GAL}/S_{NT} < 1)$ portion of the z = 1 area and the thermal $(S_{GAL}/S_{NT} > 1)$ part of the z = 0 area. Finally the areas have been plotted for two values of α ; $\alpha = 2.0$ and $\alpha = 2.5$ are the solid and dashed curves respectively.

Most of the data points lie well within the area described by the model; the $\alpha = 2.5$ case covering 16 of the 19 sources. Some of the scatter of the data in α_{KJ} will be caused by emission lines

(especially $H\alpha$ passing through the J band) and some of the scatter in α_{KB} may be caused by variability and the nonsimultaneity of the optical and IR flux measurements. However, the agreement is surprisingly good given the simple assumptions. A range of α from 2 to 3 is sufficient to cover even the most extreme sources. The assumption that $\alpha = 0$ for $\lambda > \lambda_n$ is not critical. Observations at longer wavelength will help confirm this picture.

We thank the AAO staff for helpful support, C.D.I. acknowledges the receipt of an SRC studentship.

New family of homogeneous chemical oscillators: chlorite-iodate-substrate

Miklós Orbán*, Patrick De Kepper*, Irving R. Epstein & Kenneth Kustin

Department of Chemistry, Brandeis University, Waltham, Massachusetts 02254, USA

Interest in oscillating chemical reactions arises because these systems serve as models of temporal organization in biological systems, as starting points for the development of spatial structure in initially homogeneous systems and as instructive examples of the wide variety of dynamic phenomena possible in chemical systems far from equilibrium. One obstacle to the development of a general theory of chemical oscillation has been the small number of fundamentally distinct homogeneous oscillators and the failure of efforts to design new oscillating reactions. We recently suggested a systematic approach to the construction of chemical oscillators and used it to produce a homogeneous oscillating reaction: the chlorite-iodate-arsenite oscillator1. We now report that the above system is the prototype of a family of homogeneous oscillators, all of whose members have the species chlorite and iodate in common, but which can utilize a wide variety of reducing agents or substrates in place of arsenite.

Figure 1 shows the time dependence of the potentials of an iodide-selective and a platinum redox electrode and of the absorbance at 460 nm when one-electron (ferrocyanide) and two-electron (thiosulphate) reductants react with NaClO2 and KIO₃ in the same experimental conditions in a continuous flow stirred tank reactor (CSTR). The CSTR maintains the system far from equilibrium, which is a necessary condition for sustained oscillation.

Table 1 gives the concentration range in which oscillations have been found for each of our substrates. Optimum concentrations, at whichparge amplitude oscillations are observed over a wide range of flow rates (80-2,000 s residence time), are also indicated. While the waveform and frequency of oscillation vary with the flow rate and with the nature and concentration of the substrate, relative changes in [I⁻] of 10⁴ or more in each cycle were obtained with all substrates. At the upper and lower ends of the substrate concentration range, oscillatory behaviour is observed only at relatively high or low flow rates, respectively. Above or below these concentration limits, only a single nonoscillatory steady state of high or low iodide and iodine concentrations can be observed. The transition from large amplitude

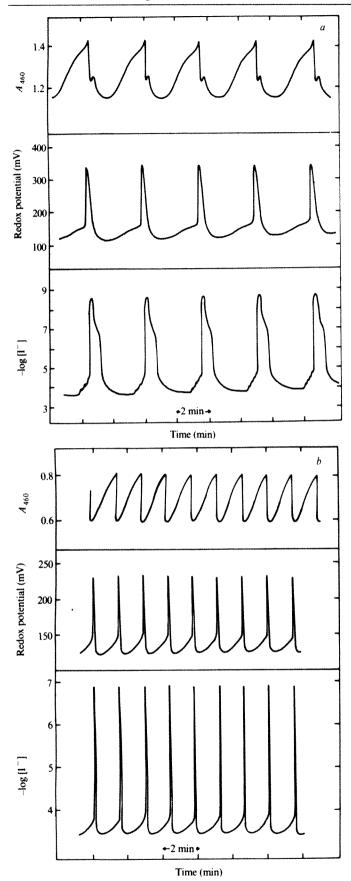

Fig. 1 a, Optical density at 460 nm, potential (compared with Hg/Hg₂SO₄ reference electrode) of platinum electrode, and [Γ] determined by iodide sensitive electrode in a CSTR with input composition (concentrations in the reactor after mixing, but before initiation of reaction), [NaClO₂]₀ = 0.002 M, [KlO₃]₀ = 0.01 M, [K₄(Fe(CN)₆)]₀ = 0.005 M. Temperature, 25 °C; pH, 2.06; residence time, 310 s. b, As in a but with ferrocyanide substrate replaced by thiosulphate, [Na₂S₂O₃]₀ = 0.005 M, and pH = 2.40.

oscillation to steady state as the substrate concentration is varied may occur either suddenly and directly or through a state of small amplitude oscillation about the steady state which is being approached.

Substrates which generate oscillations include both one- and two-electron reductants and cover a considerable range of redox potentials (see Table 1). Their common feature is apparently that they participate in a Landolt-like reaction².

$$(6/n) \operatorname{red} + IO_3^- = (6/n) \operatorname{ox} + I^-$$
 (1)

qere red and ox signify the reduced and oxidized form of the substrate, and n = 1 or 2 according to whether the substrate is a one or two electron reducing agent. Reaction (1) is autocatalytic in iodide³. The iodide produced then reacts with chlorite to yield iodine:

$$4I^{-} + CIO_{2}^{-} + 4H^{+} = 2I_{2} + CI^{-} + 2H_{2}O$$
 (2)

Reaction (2) is autocatalytic in I₂ and is inhibited by I (refs 4,5). The chlorite-iodide system gives rise to two different stable steady states in a CSTR⁶. The observed oscillation in the present reaction may then arise from the effect of the relatively slow substrate-generated feedback of iodide on the faster and intrinsically bistable chlorite-iodide subsystem. This view is based on a simple model of the relationship between oscillation and bistability due to Boissonade and De Kepper⁷.

Arsenite reacts less rapidly with iodate than do the other substrates in Table 1. Oscillation with arsenite as substrate must be initiated by the injection of a small amount of iodide into the reactor, while with the other substrates, oscillation begins spontaneously. These observations suggest that initiation of oscillations requires the production of a quantity of iodide above some threshold level.

Neither malonic acid nor iodide as substrate will produce oscillations in our conditions. Malonic acid reacts with iodate to form iodine, which slowly reacts with the excess substrate to yield iodomalonic acid and iodide. The stoichiometry of this process is such that only half as much I is produced with malonic acid as with the other substrates, and apparently an additional iodide flow is needed to produce oscillation.

The wide range of substrates examined allows us to infer several criteria for a substrate to generate oscillation in this system. The redox potential of the substrate, in the reaction conditions, should be less than that of the iodine-iodide couple (0.62 V(ref. 8)). For example, ferrous ion, hydroquinone and hydrogen peroxide, which react with iodate to yield I₂, have redox potentials of 0.77, 0.70 and 0.68 V respectively, and hence do not give oscillation.

The essential kinetic requirement seems to be an appropriate rate of iodide production either by the direct iodate—substrate reaction or by the subsequent reaction of iodine generated in the initial step with the remaining substrate. If the substrate produces iodide too slowly, then the Dushman reaction ($IO_3^- + 5I^- + 6H^+ \rightarrow 3I_2 + 3H_2O$) prevents iodide from accumulating to the point at which the autocatalytic reaction (2) with chlorite can generate a burst of I_2 to start the oscillation. Thus vanadium (III)

has a suitable redox potential ($E^{\circ} = 0.34 \text{ V}$), but gives rise only to a stable steady state with low [I]. Other non-oscillatory substrates which we have tested, such as hydrazine and hydroxylamine, seem to yield iodide too rapidly, thereby inhibiting reaction (2) and forcing the system into a steady state of high iodide concentration. Stannous ion, which seems to satisfy both our redox potential and kinetic criteria, does not give oscillation because the formation of the slightly soluble SnI₂ places a relatively low limit on the iodide concentration that can be attained in the reactor. Substrates which, for kinetic reasons, do not give oscillations in the present conditions, may prove oscillatory in different conditions.

Further studies under way in this laboratory on the detailed mechanism of these systems will hopefully reveal more about the role of the substrate in the family of chlorite-iodate-substrate oscillators.

The hydrophobic and organophilic nature of silicalite may prove commercially important for the removal of organic compounds from waste water. The framework linkage of silicalite¹ is topologically the same as that of synthetic zeolite ZSM-5 (ref. 2), a shape-selective catalyst³ capable of converting methanol into water and hydrocarbons useful in automobile engines4. The tetrapropylammonium (TPA) fluoride (F)containing precursor to fluoride-silicate⁵ crystallizes from a hydrothermal system containing silica, TPA+ and F- ions. Destruction of the organic cation during heating in air gives fluoride-silicalite, a polymorph of silica with some properties similar to those of silicalite^{1.5}. We show here how a TPAF complex in the precursor lies at the tetrahedral intersection of the 10-ring channels of a silica framework in a position consistent with a template scheme for crystallization⁶. There is not enough space to permit replacement of TPA by the tetra-nbutyl ammonium complex used in the synthesis of ZSM-11 (ref. 7) and its silica counterpart, silicalite-2 (ref. 8)

Crystals of the precursor are interpenetrant twins elongated along the c-axis $(180 \times 50 \times 50 \mu m)$. The twin boundaries are $\{(110)\}\$ and the twin law is 90° rotation about [001]. Singlecrystal X-ray and optical studies yielded monoclinic symmetry $(a, 20.04; b, 19.92; c, 13.39 \text{ Å}; \beta \sim 90^{\circ})$. Because of the nearequivalence of the a and b axial lengths, the twinning causes near-superposition of hkl and khl diffractions. The intensities of over 12,000 diffractions, each an hkl, khl pair, were measured over one quadrant of reciprocal space (Mo $K\alpha$ radiation) using a four-circle diffractometer. In spite of the optically monoclinic symmetry, the intensities are consistent with orthorhombic space group Pnma used for the refinement of silicalite⁹. The following structure description uses this space group and an

orthorhombic cell with the above cell dimensions. Averaged intensities for 1,645 unique diffractions with $F_{\rm obs} > 2\sigma$ allowed refinement of the silica framework to R = 0.10 with a special least-squares program TWXLLS. The combined intensity of pI(khl) + (1-p)I(hkl) for a pseudo-tetragonal twin was split into the individual intensities I(hkl) and I(khl) for the pseudoorthorhombic structure where the fractional volume p of one twin component was refined from all the intensities. A difference-Fourier synthesis revealed one organic complex at each of the four intersections of the 10-ring channels (Fig. 1), corresponding to a unit cell composition of 4 TPAF.96 SiO₂. Least-squares refinement yielded R = 0.07 and the atomic coordinates in Table 1. The coordinates of the silica framework are similar to those for silicalite9. Because of the restricted data set and some disorder of the TPAF complex, individual isotropic displacement factors were used for the framework atoms and a single displacement factor for the TPAF. No significant electron density was found in a difference-Fourier map based on the coordinates of Table 1.

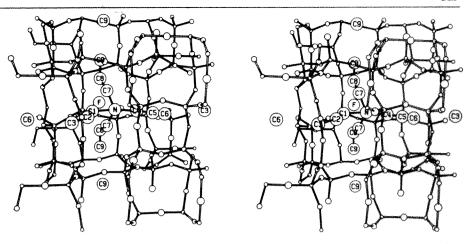

The silica framework has a mean Si-O bond length of 1.60 Å (σ 0.04) and a range of Si-O-Si angles of 136-178° about a

Standard deviations for Si, O and non-framework atoms are ~0.0006. 0.001 and 0.005 respectively.

Fig. 1 Stereoview of TPA-F complex and adjacent atoms from the silica framework. ORTEP plot with spheres at 20% probability level.

mean of 153.6° (σ 11.4). A negative correlation between Si-O bond lengths and secant (Si-O-Si) for the 4-coordinated silica polymorphs¹⁰ was interpreted in terms of overlap of molecular orbitals. The present structure shows a similar relationship with slope 0.13 (correlation coefficient 0.6), close to that predicted theoretically for a silica cluster in Fig. 8a of ref. 11.

The tetrahedral configuration of the four propyl limbs of the TPA ion and the close coordination of the fluoride to the central nitrogen at 2.52 Å and four carbons all at 2.21 Å is physically reasonable and resembles that in the crystal structure of TPAbromide¹². Two propyl limbs partly enwrap the fluorine, and a fifth carbon atom from a third limb lies at 2.75 Å to the fluorine atom. Because hydrogen bonds involving F span a range 13 of 2.3-2.8 Å which almost encompasses the above distances, the fluoride ion is probably held in place by hydrogen bonding.

The neat fit between the TPAF complex and the internal surface of the silica framework is consistent with a template mechanism for crystallization⁶. Furthermore, the end carbon atom of each propyl limb lies at 2.8-3.1 Å to the end carbon atom of the propyl limb from the next TPAF complex, and there would not be enough space for a butyl limb. Although there are no published atomic coordinates for the structures of ZSM-11 (ref. 7) or its silica counterpart, silicalite-2 (ref. 8) which can be synthesized from tetra-n-butylammonium-containing systems, models with plausible geometry show that the channel intersections are larger than for the ZSM-5 and silicalite type of linkage, and in particular are large enough for a butyl-bearing complex. Knowledge of the structural interactions between tetrahedral frameworks and occluded complexes should prove useful in designing conditions for crystallization of useful shapeselective catalysts.

Further data are being collected to increase the precision of the atomic coordinates. The cause of the monoclinic symmetry is also being investigated. The present study has indirect implications for various inorganic-organic complexes, including ones involving clays14 and biologically important compounds.

We thank R. L. Patton for providing the crystal. We thank NSF for grant CHE 78-26579, and R. Draus and I. Baltuska for technical assistance. T. A. thanks P. B. Moore for NSF grant EAR 19483. X-ray facilities are partly supported by the Materials Research Laboratory (NSF).

Dehydration-induced luminescence in clay minerals

L. M. Coyne, N. Lahav & J. G. Lawless

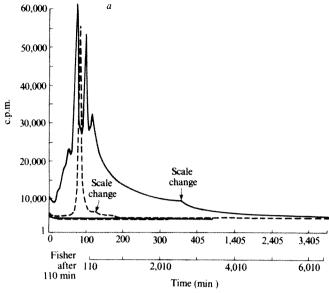

Ames Research Center, NASA, Moffett Field, California 94035, USA

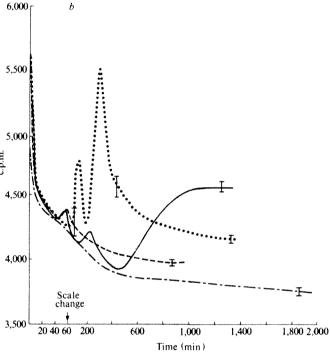

Reports of triboluminescent phenomena in organic crystalline materials1,2 prompted us to look for related processes in clay minerals. We found the reported extensive mechanical distortion produced on freezing and drying of montmorillonite particularly interesting because of our studies of condensation reactions in a wet/dry cycled reaction sequence4-7. We now report the discovery of an unusual luminescent process in several clay minerals and describe its characteristics.

We have found that blue to near UV photons are emitted when a thin layer of an aqueous suspension of certain clays is dried over a desiccant or by gentle heating to 85 °C (ref. 7). Figure 1a-c shows typical examples of three distinctive patterns of photon release as a function of time. The patterns are: (1) a delayed burst, (2) a delayed rise to a slowly decaying plateau and (3) a simple monotonic (exponential-like) decay from the time of introduction of the desiccant.

Kaolinites show an initial monotonically decaying emission of photons followed, some minutes to hours later, by the delayed burst. Two examples are shown in Fig. 1a, Fisher kaolinite and Mesa Alta rock, ground in a mortar and pestle a few days before sample preparation. A similar pattern of emission was observed from all other kaolinites examined; Peerless no. 2: kaolin no. 53 from Birch Pit, Macon, Georgia, and kaolin no. 17 from Lewistown, Missouri. The photon yield and relative proportion of monotonic to delayed emission varied from kaolinite to kaolinite. The time of onset of the burst is increased by a thicker film. The light is released when the average moisture content approaches 40% H₂O. The significance of this moisture content with respect to water content at the drying front is uncertain, but the average range is within the quoted range for the adsorption and long-range ordering of water by kaolin8. Multiple peaks are frequently observed, especially in the non-commercial kaolinites; the peaks seem to be largely, but not fully, explained as experimental artefacts resulting from non-uniformity in the thickness of the clay film and the size of the particles.

The amount of light released on dehydration is an approximately linear function of the amount of kaolin, up to a film thickness of $\sim 10 \,\mu m$ (as calculated from the dry weight of kaolin, the exposed surface area of the emitting film and its estimated density), after which self-absorption and scattering produce a gradual saturation⁷. Light release can be regenerated by repeated cycles of wetting and drying, up to at least four cycles, or until deterioration of the clay film prevents further trials.

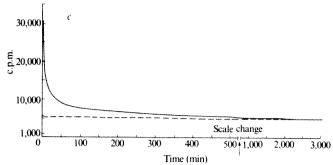

Emission from three halloysites is shown in Fig. 1b. Bedford shows weak emission and Wagon Wheel shows a pattern similar to that of the kaolinites, but with considerably reduced photon yield. Dragon Iron, however, gives a third characteristic mode of emission: the customary initial monotonic decay is followed by a relatively rapid rise to a slowly diminishing plateau. All three halloysites are colourless, relative to the 2:1-layer clays.

Of several 2:1-layered clays examined, none has shown a delayed peak. For example, montmorillonites, illites and a mica show stronger monotonic components of emission than kaolinites, but no delayed burst. This general form of emission is also characteristic of the attapulgites examined, an example of which is shown in Fig. 1c. These clays are more highly coloured than the kaolins; therefore, absence of the delayed burst may be attributable to reabsorption depending on the spectral properties of the different components of the emitted light. However, as the monotonic component is commonly enhanced relative to that in the kaolins, it is reasonable to assume that the differences also imply structurally dependent differences in the modes of emissive relaxation of the materials.

The relative proportion of light emitted as the delayed and as the monotonic components is a sensitive function of a variety of treatments and clay sources. The monotonic component is

Dehydration-induced luminescence of several clays. a, Kaolin no. 9 from Mesa Alta, New Mexico, Wards 48 W 0290 and background (Vial+Drierite) for same—upper timescale (note scale change after 300 min); ---, kaolin, Fisher lot no. 753828 and background (Vial + Drierite) for same—lower time scale after scale change at 110 min. b, -, Halloysite no. 13, Dragon Iron Mine, Eureka, Utah; ---, halloysite no. 29, Wagon Wheel Gap, Colorado; ..., halloysite no. 12 48 W 0120, Bedford (Huron), Indiana, North Gardner Mine; -Vial and desiccant background. (The curves for Bedford and Wagon Wheel halloysites have been displaced upwards slightly, for clarity of presentation. The return to hackground is actually within -, Attapulgite of unknown origin; ---, empty tube and tube+drying agent. Luminescence from a clay-water paste (1:1-1:3) was measured as a function of desiccation over CaSO₄ or silica gel. The photon output, integrated over the spectral sensitivity of the EMI 9635 QB Phototube (maximum sensitivity at 3,700 Å), was measured in a Packard 3320 Tri-Carb liquid scintillation counter in the anticoincidence mode with a 50-1,000 window on the discriminators and full gain. Photon output was displayed on a Davidson model 10565 B multichannel analyser. The paste was applied uniformly around the interior of Pyrex scintillation vials, which were scrupulously cleaned in boiling nitric acid and rinsed repeatedly with triply distilled water, air-dried and stored, with their caps, in the dark. Vials were wiped with a damp towel before counting to reduce spurious count-rate from static electricity. Common photon counting artefacts, such as luminescence from the vial, the vial cap or the desiccant, lack of temperature equilibration, and heat release from the wetted desiccant, are negligible after the first 10-30 min, as is clear from the accompanying backgrounds of empty vial and empty vial plus Drierite, and the following three controls. (1) The integrated count rate from the cooling of hot (70 °C) water to the temperature of the counter (10 °C) was 300 counts per g H₂O. (2) The integrated count rate from the addition of water to Drierite was 40 counts per mg H₂O. The clay samples typically contained 30-200 mg of clay and thus 60-400 mg H₂O. Typical peaks had an integrated count of 10⁶ counts. (3) No appreciable activity is seen from pastes contained in vials that have been painted black.

increased by orders of magnitude by prior γ -ray irradiation and grinding. In freshly ground samples, it is increased severalfold by a 10-min sonication of the clay/water paste immediately before application. Sonication may simply produce a paste of more uniform particle size by increased dispersion of the larger particles, rather than cause an electronic excitation, but the grinding effect is definitely of triboluminescent origin; this will be reported elsewhere.

An important feature of the delayed peak, with respect to its potential relationship to clay structure-reactivity correlations, is its dependence on the thermal history of the clay. Figure 2 shows the total photon output in the delayed peak after preheating to different temperatures. Heating to temperatures above 500 K temporarily destroys the luminescent effect. Samples of Fisher kaolin preheated to 650 and 1,000 K were remeasured after 6 months, with considerable restoration of the delayed peak in the 650 K sample, but none in the 1,000 K sample. Heating to 650 K for 1 h would not be expected to dehydrate kaolinite irreversibly, but similar heating to 1,000 K would probably result in considerable irreversible dehydration 10 . Preheating results in diminution of luminescence induced by both dehydration and grinding. Preliminary results suggest that destruction by preheating, and restoration by γ -ray irradiation, of the

capacity of the material to produce delayed luminescence may resemble similar destruction and restoration of centres active in electron spin resonance which have been identified in natural and doped synthetic kaolins11

Because of the low overall emissivity of the highly isomorphously substituted 2:1-layer clays and the intermediate emissivity of halloysites relative to kaolinites, we tentatively associate differences in the luminescent yield with those structural parameters that affect the relative magnitude of clay platelet-water and clay platelet-clay platelet attractions such as geometry of platelet stacking or isomorphous substitution. Verification of this hypothesis will rest on detailed study of the relationship between the rate of water loss and photon yield as a function of time in additional specially characterized and purified clays, as clays are notable scavengers, adsorbing and occluding a variety of organic and inorganic materials.

Similar measurements of luminescence have been made on several other naturally occurring, commercially available inorganic compounds such as: TiO2, a common contaminant of kaolin; Al₂O₃ and SiO₂, the chemical constituents of the layered silicates under investigation; hydroxyapatite, a substance with similar high positive-charge deficiency in the crystal lattice; and CaCO3, with its characteristic complex thermoluminescent behaviour 12-14, which we have shown to be more active than kaolin in producing glycine condensation in prebiotic simulation experiments7. These materials exhibited no delayed burst and considerable reduction in the monotonically decaying component of light emission. However, calcite, prepared for the measurements by grinding, shows the exponential-like behaviour. Solid material remaining after a 1-week digestion of Fisher kaolin in concentrated HCl showed multiple delayed photon-emission bursts of three-to six fold diminished overall intensity (not shown).

Much work remains in characterizing the spectroscopic properties of the effect-its wavelength dependence, the photon yield, the temperature dependence of the light output, molecu-

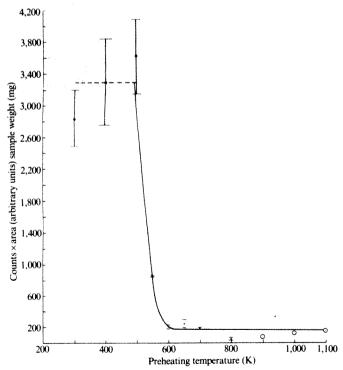

Fig. 2 Effects of preannealing on photon output from kaolin. Samples were heated by placing in a Thermolyne CPS-A8720 oven with a Dubuque III solid-state temperature controller, equilibrated to the nominal temperature, where they were held for ~ 1 h. Cooling was facilitated by partial opening of the oven door. Samples were removed when the temperature had dropped to below 500 K. The dashed line indicates uncertainty as to whether the apparent rise from room temperature to 500 K is real or an experimental uncertainty.

lar or atomic details of the trapping site or sites, mechanisms of trap population and energy release, and the relationship between monotonic and delayed emission.

Preliminary studies of the ability of preheated kaolin to produce peptide bonds under the fluctuating reaction protocol indicate an anti correlation between capacity to produce light and capacity to produce peptide bonds; luminescence may well represent wastage of chemically useful energy. Establishment of a relationship between stored electronic energy and the ability of clays to promote chemical reactions would be important to clay chemistry, not only with respect to catalysis in laboratory systems, but also to chemistry in present and past natural environments

We thank H. Nishita for providing clay samples and for continued interest in the research. L.M.C. acknowledges a Senior NRC Research Associateship. Helpful suggestions in preparing the manuscript were made by Ruth Mack, S. Mead, S. Chang and Neal Blair.

(100) Deformation twins in naturally deformed amphiboles

C. Biermann

Geologisch Instituut der Universiteit van Amsterdam, Nieuwe Prinsengracht 130, Amsterdam, The Netherlands

The occurrence of growth twins with (100) as a composition plane has been well established in clinoamphiboles, but no evidence has been presented that (100) twins may form by natural deformation. We now report that in naturally deformed hornblende crystals, selected from an amphibolite mylonite in the Central Scandinavian Caledonides, lamellar (100) deformation twins have been identified using optical and transmission electron microscopy (TEM). The lamellar twins are present within highly bent and kinked parts of the hornblende crystals. Selected area diffraction patterns show that twin and matrix domains are related by a 180° rotation about a^* . Additional defects associated with the (100) planes are unit dislocations with $\bar{b} = [001]$ and stacking faults bounded by partial dislocations. The identification of (100) mechanical twins in clinoamphiboles illustrates the similarity in mechanical twinning behaviour of clinoamphibole and the related clinopyroxene structure.

Deformation experiments on single crystals of clinoamphibole have been described elsewhere 1-7. The dominant mode of deformation in these experiments is mechanical twinning on $(\bar{1}01)$ in the C2/m setting of the unit cell. Natural occurrences of (101) deformation twins are rare, having only been reported from shock-loaded rocks^{8,9} and in extremely deformed amphibole gabbro from the Ivrea-Verbano Zone in the Alps⁶.

The absence of mechanical (100) twins has not been understood in terms of the crystal structure. In the related clinopyroxene structure two types of mechanical twins occur¹⁰. In experimentally deformed and shock-loaded rocks (001) twins form the analogue with $(\bar{1}01)$ twins in clinoamphibole 11.12. The

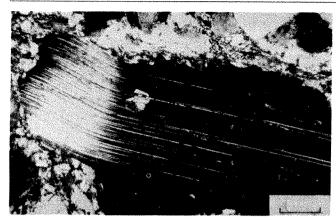

Fig. 1 Bending of a hornblende crystal is accompanied by numerous (100) deformation twins. Amphibolite mylonite Kittelfjäll. Crossed polarized light. Scale bar, 0.1 mm.

(001) plane in clinopyroxene (C2/c) is structurally related to the $(\bar{1}01)$ plane in clinoamphibole (C2/m). In naturally and experimentally deformed clinopyroxene thin lamellar (100) twins are common. There has been no proof that mechanical (100) twins are present in naturally deformed amphibole, although Kirby and Christie¹⁰ have suggested that (100) polysynthetic twins in natural amphiboles may be mechanical in origin. On the other hand, Dolinger and Blacic¹⁴ concluded that (100) [001] slip operates during kinking of hornblendes in experimentally deformed igneous hornblendite and they suggest that (100) [001] slip prevents the occurrence of (100) twinning as it is activated at a lower critical resolved shear stress.

The material described here was selected from a mylonite zone in the basal part of the Kittelfjäll amphibolite massif¹⁵ in the Central Scandinavian Caledonides. The mylonite zone separates the Kittelfjäll amphibolite from the underlying Kittelfjäll peridotite¹⁶. Both lithological units are part of the Seve Nappe, one of the major nappe structures in the Scandinavian Caledonides¹⁷. The mylonite zone formed during the late stages of the Caledonian deformation history at a lower greenschist facies metamorphic regime at intermediate pressures.

Several rock types are present within the mylonite zone, but amphibolites are dominant. In thin section the individual amphiboles are often fractured, bent or kinked, showing numerous lamellar features. The presence of lamellae within the individual crystals is consistently associated with the bent and kinked domains and their number increases towards the more intensely deformed areas (Fig. 1). Based on these observations it was concluded that the lamellae are related to deformation.

Using the optical microscope the crystallographic orientation of the lamellae was shown to be parallel with (100). In sections

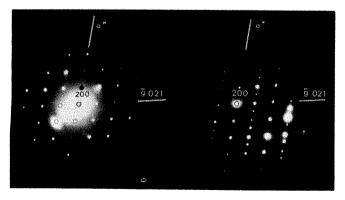

Fig. 2 Selected area diffraction patterns showing the simple pattern of an area from a matrix domain (left) and the complex pattern of an area across the twin interface (right). The extra spots originate from the spots in the left hand pattern by a 180° rotation about a^* . The trace of the twin interface in the corresponding TEM micrograph (not shown) is oriented perpendicular to a^* .

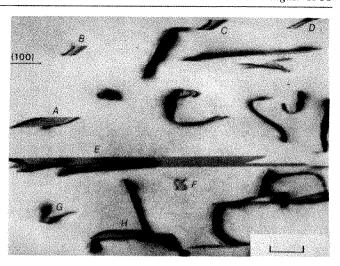

Fig. 3 Partial dislocations at the termination of stacking faults at (A-H). The stacking fault fringes are oriented parallel to the (100) composition planes of the twins. Scale bar, $0.1 \mu m$.

through the crystals parallel to the c-axis the trace of the lamellae extends parallel to the prismatic cleavage. In a few cases the lamellae have also been observed in sections perpendicular to the c-axis. The trace of the lamellae in these sections is parallel to the acute bisector of the dominant $\{110\}$ cleavage planes. When observed in the electron microscope the lamellae appear as long domains, $<20\mu m$ wide, and bounded by planar coherent interfaces. Chemical analyses on thin foils 18 , using an EDAX analytical system, showed no chemical differences between adjacent domains 13 . Selected area diffraction (SAD) showed the twin relation between the adjacent domains. SAD patterns across vertically aligned interfaces produced Laue zones, that contained extra spots, symmetrically distributed with respect to the h00 row of reflections (Fig. 2). These extra spots were not present in the electron diffraction patterns from areas selected from a single twin domain.

The $h\,00$ row of reflections in the complex pattern is common to the diffraction patterns of material at both sides of the interface. The extra spots are related to those of the diffraction pattern from a single twin by a 180° rotation about a^* . This systematic relationship persisted for all diffraction patterns in which the interface was vertical. Dark-field imaging, using twin and matrix reflections, confirmed the above interpretation. In all SAD patterns of areas with vertically aligned twin interfaces the $h\,00$ row of reflections was perpendicular to the trace of the twin interface in the corresponding TEM images, thus confirming the (100) orientation of the twins.

Additional defect structures observed in the samples are long segments of dislocations parallel with the trace of the (100) planes. Contrast experiments on these dislocations show invisibility for $\bar{g}=020$ and minimum contrast for $\bar{g}=200$. It is suggested that the Burgers vector of these dislocations is [001], confirming the slip system identified by Dolinger and Blacic¹⁴ using optical measurements and by Morrison-Smith¹⁹ using TEM. Stacking faults parallel with (100) are present in these samples and are bounded by partial dislocations (Fig. 3).

Mechanical ($\overline{101}$) twins have not been found in the Kittelfjäll amphibolite mylonites. Mechanical twinning on ($\overline{101}$) does not in general seem important in the natural deformation of clinoamphiboles. Various authors ^{14,19} have demonstrated (100) [001] slip, and the observations on the material described here confirm their conclusions.

The mechanism for the formation of (100) mechanical twins is considered to be the same as that described for clinopyroxene 10 . The essential difference between the clinopyroxene and clinoamphibole structure is the presence of double layers of SiO₄ tetrahedrons in the amphiboles. Consequently the b-parameter of the amphibole unit cell is approximately twice that of clinopyroxene, but there are no important differences in the

plane perpendicular to [010]. The geometry of (100) mechanical twinning in clinopyroxene requires the more or less rigid translation of tetrahedral layers by $\frac{1}{2}c$, resulting in an appropriate simple shear deformation of the octahedral layers in between. The composition plane in this model is therefore situated in the tetrahedral layer, which connects the sheared and unsheared octahedral layers. In addition, small shuffles are needed to obtain the exact twin geometry. The twinning shear can be propagated by the movement of partial dislocations with \bar{b} = $\frac{1}{2}[001]$, gliding in the octahedral layer¹⁰. The symmetry operator that is present in the tetrahedral layer of the C2/m clinoamphibole structure, is a diad screw axis parallel to b. The twinning mechanism described above will therefore result in a deformation twin with b-glide symmetry on (100).

The study of the deformation behaviour of crystalline silicate materials has become important since interest has concentrated more and more on fundamental mechanisms of deformation. The material from the Kittelfjäll amphibolite mylonites proves that (100) mechanical twinning is a possible mode of deformation in naturally deformed clinoamphiboles. identification of these twins confirms the similarity in twinning behaviour of clinoamphiboles and the related clinopyroxenes.

Increase of CHClF₂ in the Earth's atmosphere

M. A. K. Khalil & R. A. Rasmussen

Department of Environmental Science, Oregon Graduate Center, 19600 NW Walker Road, Beaverton, Oregon 97006, USA

Ambient air collected and stored in calibration tanks with inert internal surfaces was analysed by the electron capture-gas chromatography techniques (EC-GC) for measuring CHClF₂ (fluorocarbon-22 or F-22) at atmospheric concentrations of between 30 and 60 p.p.t.v. (10^{-12}) . Repeated measurements of F-22 in these tanks over the past 18 months have shown no significant changes in concentration, implying that the measurements reflect the atmospheric concentrations of F-22 when the air was collected. The resulting time series, based on 360 measurements made on 100 different samples, shows that CHClF₂ concentrations increased at an average exponential rate of 11.7% yr⁻¹ (90% confidence limits: 9.8%-13.2% yr⁻¹) between April 1976 and January 1981. Based on this time series, it is shown here that a constant 200×10^6 kg of F-22 in the Earth's atmosphere cannot be accounted for by the global anthropogenic emissions estimated by McCarthy et al. 1.2. This excess is ~26% of the estimated present global burden of F-22 in the entire atmosphere.

Since the early 1950s, emissions of the inert man-made fluorocarbons CCl₃F (F-11) and CCl₂F₂ (F-12) rose rapidly until 1974, when Molina and Rowland³ proposed that chlorine atoms from the dissociation of these gases could ultimately destroy enough of the Earth's stratospheric ozone layer to affect human health adversely by allowing more UV radiation to reach the Earth's surface. Subsequent theoretical studies also concluded that the large expected accumulations of these gases from continued anthropogenic emissions would lead to a global warming of the Earth's surface, which could cause climatic changes and affect agriculture^{4,5}. In the US these concerns led to restrictions on unessential uses of F-11 and F-12 and a search for substitutes. The National Academy of Sciences (NAS)6 suggested that F-22 would be safer for the ozone layer, because it contains only one chlorine atom and some of the F-22 is destroyed in the troposphere by reactions with hydroxyl radicals (HO). The NAS report also cautioned that "... if current trends in the rapidly increasing use of F-22 and methyl chloroform continued unabated, the release rates and atmospheric behaviour of these compounds will require careful attention". F-22 emissions have been increasing rapidly^{1,2}, but so far the total emissions and the atmospheric concentrations remain much less than those of CCl₃F, CCl₂F₂ and CH₃CCl₃. Continuing increases in the emissions of F-22 could, however, lead to a large accumulation in the Earth's atmosphere, partly because it reacts slowly with the hydroxyl radicals, resulting in an atmospheric lifetime of ~ 20 yr (ref 7.). It is believed that reaction with HO radicals is the major global sink of F-22. Furthermore, F-22 efficiently absorbs outgoing IR radiation at wavelengths of ~7.5, 9 and 12 µm (ref. 8) which are, as for CCl₃F and CCl₂F₂, in a region of the spectrum where natural atmospheric gases absorb little of the outgoing radiation. Thus, the general

Monthly average concentrations of CHCIF2 (F-22) over the US Pacific Northwest (~45 °N). . Average concentration line derived by nonparametric statistical methods. Concentrations expected on the basis of global emissions. The error margin for this line is quite large. It is conceivable that when the error estimates are better defined, the two lines will come closer together.

behaviour of F-22 in the Earth's environment is expected to be similar to that of F-11 and F-12, although the magnitudes of possible environmental perturbations may be less and have yet to be determined quantitatively.

The first measurements of F-22 in the atmosphere were made in 1979 by gas chromatography-mass spectrometry (GC-MS) and EC-GC techniques9. Ambient air collected periodically since early 1976, before it was possible to measure F-22 at the atmospheric concentration of 30-60 p.p.t.v, had been stored in tanks with inert internal surfaces.

Measurements to obtain a time series were made on about 100 different samples collected between April 1978 and January 1981. An in-situ air liquefaction method, which introduces no trace halocarbon contamination, was used to compress about 1,000 l of air at STP to 450 p.s.i.g. and store it in 35 l stainless steel tanks internally passivated by the SUMMA process. The water condensed in the tanks was drained and before analysis the air was further dried to less than 1% RH by a Nafion dryer. The results we report here are F-22 concentrations in dry air.

We believe that the measurements reflect the atmospheric concentrations of F-22 at the time of collection because since we first measured F-22 in the atmosphere more than a year ago, we have made repeated measurements of F-22 in each of our tanks and found no statistically significant systematic changes of concentrations. Random variabilities, however, typically <4% of the initial concentrations, were observed. In addition, repeated measurements over the past 3.5 yr have shown that CCl₃F, CCl₂F₂, CH₃CCl₃ and N₂O have all remained at constant concentrations in all the tanks used for this study, thus establishing the stability of long-lived trace gases in our tanks. These experiments also showed that the precision of analysis was good (estimated $\sigma = 2\%$ and 4% for two tanks studied intensively) whereas the absolute accuracy assigned to the primary standard is only $\pm 10\%$ (estimated σ) (see also ref. 7).

Figure 1 shows the atmospheric concentrations and the increase of F-22 in the atmosphere at 45 °N latitude in the US Pacific Northwest. The rate of increase, obtained by non-parametric statistical methods ¹⁰, is given in Table 1 and shown in Fig. 1. The statistical techniques used are less sensitive to a few extreme deviations than the classical methods, and the evaluation of the increase by $(1/C)dC/dt = \beta$, where C is the concentration and β the rate of increase, is not sensitive to errors of absolute accuracy.

Next, we estimated the concentrations to be expected from the estimated industrial release of F-22 since 19506.

Concentrations determined by a global mass balance were corrected for latitude variation of F-22 and for the amount in the stratosphere⁷ to arrive at the concentrations expected at 45 °N latitude¹¹, which are shown in Fig. 1. [The techniques are discussed in ref. 7. It was assumed that the lifetime of F-22 is 20 yr, and that the ratio of $C(F-22 \text{ at latitudes} > 45 ^{\circ}\text{N})$ to C(F-22 at)latitudes < 45 °S) ≈ 1.3 as determined by measurements made at several times at the south pole, Tasmania and Cape Meares. Oregon, as well as the measurements reported in ref. 9.] We found that the concentration expected on the basis of anthropogenic release estimates is less than that determined by atmospheric observations. We defined the difference as

$$\Delta(t) = C_{\text{obs}}(t) - C_{\text{theor}}(t) \tag{1}$$

The Δ at 45 °N was found to be approximately constant with an average value $\bar{\Delta} = 17$ p.p.t.v. (estimated $\sigma = 3$ p.p.t.v., estimated $\sigma/\sqrt{N}=0.6$ p.p.t.v.). Extrapolating to global scales this amounts to about 200×10^6 kg more F-22 in the Earth's atmosphere than can be accounted for by anthropogenic emissions, and this excess amount has remained nearly constant for the past 4 yr. The independent global F-22 measurements reported earlier9 showed the same excess in May 1979. The expected rate of increase since 1976, based on estimates of global emissions, is nearly 16% yr⁻¹, which is faster than the upper limit of the observed rate of increase ($\sim 13\% \text{ yr}^{-1}$). This result also suggests that the disagreement between observation and theory is not given by a proportionality constant as would be expected from errors in absolute calibration.

We believe that the most probable explanation for the observed excess is that past industrial releases of F-22 have been underestimated. According to the release estimates of McCarthy et al. $^{1.2}$, only $\sim 41\%$ of the F-22 produced has been released compared with ~85% release/production ratio for CCl₃F and CCl₂F₂, thus allowing for a greater margin of error in the release estimates. If, for instance, we assume that the release to production ratio is $\sim 50\%$ rather than 41%, the discrepancy between our observations and the expected burden disappears. As the published release estimates considered only the production of F-22 used in refrigeration and did not include uses of F-22 as a chemical intermediate for the production of compounds such as polytetrafluoroethylene (PTFE), the amount released may have been underestimated. Estimates of F-22 emissions from eastern Europe, the USSR and China¹¹ are also subject to large uncertainties. Alternative explanations include a possible conversion of CCl₂F₂ to CHClF₂ on sand, particle and other surfaces¹², natural emissions¹³, possible errors in absolute calibration or slow losses of F-22 in the calibration tanks as well as inadequate data on the latitudinal and height distributions of F-22. Work is now in progress to determine the causes of this

Cosmogenic ¹⁰Be concentrations in Antarctic ice during the past 30,000 years

We have previously discussed how measurements of the isotope ¹⁶Be (half life 1.5 Myr) in geophysical reservoirs can be used to probe variations in the production rate of cosmogenic nuclides^{1,2}. Such variations can be caused by changes in the primary cosmic ray intensity, the geomagnetic field intensity3, and solar activity (through the modulating influence of the solar wind)4. We report here the first significant measurements in our programme to determine the 10 Be concentration profile over the entire length of a 906-m Antarctic ice core. The results suggest an increased production of 10 Be during the Maunder minimum, a period of apparently low solar activity lasting from 1645 to 1715 . More suprisingly, we have also found a substantially increased ¹⁶Be concentration in snow deposited during the last ice age. While the interpretation of this latter effect is not yet clear, it will almost certainly have important implications for climatology studies. If production variations are indeed involved, there are also important implications for solar-terrestrial relationships and radiocarbon dating.

The measurements were carried out on samples from a 906-m ice core at Dome C (74° 39'S, 124° 10'E) in Antarctica6, and from a 180-m core taken a few metres away 1 yr later. We have previously reported some preliminary measurements from the 906-m core, using 10Be extracted from meltwater filters in the field2. However, additional studies using laboratory extracted ¹⁰Be from ice at the same depths showed that the laboratory extracted experiments often gave higher concentrations. We are not sure whether this is due to adsorption during recovery of the meltwater, or whether the small quantity of ion-exchange resin in the filters became saturated with impurities during the filtering process. All results reported here were made on ¹⁰Be extracted from ice in the laboratory. Some results from the upper 250 m of the cores have been reported elsewhere.

Samples consisted of 1-3 kg of ice, each representing at least 10 yr accumulation to minimize possible 11-yr solar cycle effects. The ice was melted in plastic containers, together with 1.5 mg of Be carrier. The Be was then recovered by passing the water through Dowex 50W-8X, 200-300-mesh ion-exchange columns. The Be was eluted with 1.5 M HCl, and then converted to BeO pellets, as described in ref. 1. The technique of measuring the ¹⁰Be/⁹Be ratio using the Grenoble cyclotron to determine the 10Be concentration in the ice, has been outlined elsewhere^{2,3} and a more detailed description is given in ref. 10.

The results from 33 samples are shown in Figs 1 and 2. The ages of the samples have been estimated from previous studies on these cores (ref. 11 and M. Pourchet, personal communication). Figure 1 shows results for samples corresponding to the past ~1,000 yr. Our objective was to see whether we could see any medium term (~ 100 yr) concentration variations, such as those observed for ^{14}C in tree rings 12 which are attributed to solar modulation effects. Although the errors are rather large, we do apparently see an enhanced 10Be concentration about the time of the Maunder minimum (given by Eddy⁵ as lasting from 1645 to 1715). There are not enough points to test whether or not there is evidence for earlier variations such as the Sporer and Wolf minima, and Medieval maximum¹².

Although the experimental uncertainties on the present measurements are quite large, the suggested enhancement during the Maunder minimum (~50%), gives some idea of the potential sensitivity of this procedure for detecting modulation effects. Thus, it is hoped that, not only will it be possible to investigate such variations much further back in time than with 14C tree-ring data, but also that one could establish whether the 11-yr solar cycle itself was operating during such times4.

Figure 2 shows results over the whole length (in metres of ice equivalent) of the available cores (for clarity, the 20 points of Fig. 1 have been averaged, and are shown by the open symbol). At depths of more than ~400 m, the ¹⁰Be concentration is 2-3 times larger than in the upper part. Figure 2 also shows a smoothed curve of the $^{18}{\rm O}/^{16}{\rm O}$ ratio (given as $\delta^{18}{\rm O}$) measured in the same core¹¹. This ratio is indicative of the temperature at which precipitation occurred, and the large change at ~400 m is believed to correspond to the end of the last ice age, ~10,000 yr ago¹¹. Thus the concentration of ¹⁰Be in precipitation in the Antarctic was considerably greater during the last ice age. There are at least three possible explanations for such a situation.

The first, and perhaps the most probable, is that the general rate of precipitation in the Antarctic was much less during the last ice age. Robin¹³, for example, suggests that precipitation in the Antarctic is limited by the saturation vapour pressure of H₂O in the atmosphere. He states that a 7 °C decrease in the average atmospheric temperature, which corresponds approximately to that estimated on the basis of 18O/16O data11, would be likely to "halve the accumulation rate of precipitation" 13. The adopted chronology of Lorius et al. 11, based on correlation of identified 18O/16O features with 14C dated sediments and the ¹⁸O/¹⁶O variation, assumed a 25% decrease in the precipitation rate beyond ~15,000 yr BP. To account for the ¹⁰Be results by this phenomenon, the decrease would have to be considerably greater.

A second explanation related to meteorology is that the circulation pattern in the atmosphere during the ice age led to a greater fraction of the global production of ¹⁰Be going into the Antarctic troposphere. This is possible because the largest part of ¹⁰Be (and other cosmogenic isotope) production is in the stratosphere14. How these isoptopes reach the Earth's surface depends on the details of stratospheric-tropospheric exchange processes. The features of such transfer which control cosmogenic deposition in Antarctica, are not well understood1

The third possibility for the increased 10Be concentration during the last ice age is that the explanation is the same as that for the increase during the Maunder minimum, that is, reduced solar activity, leading to increased 10Be production. If this were the case, one would be tempted to speculate on a causal relationship. The possible connection between reduced solar activity during the Maunder minimum and the 'Little Ice Age' has been discussed extensively 16-19.

Fortunately, there are ways of testing which of the above explanations for the increased ¹⁰Be concentration is correct. If lower precipitation is the answer, then clearly the ice at the bottom of the Dome C core is considerably older than the present estimate (~50,000 BP instead of ~30,000 BP). Some

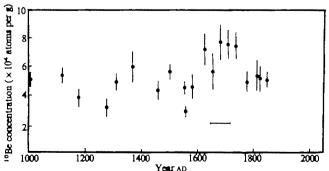

Fig. 1 ¹⁰Be concentration in Antarctic ice at Dome C. The solid line corresponds to the Maunder minimum (1645-1715, according to Eddy³).

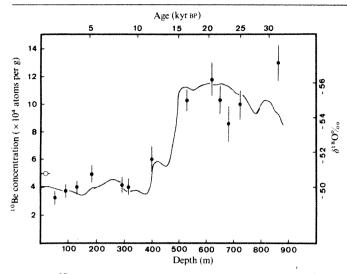

Fig. 2 $^{-10}$ Be concentration (data points, left-hand scale) and δ^{18} O (solid line, right-hand scale) in ice at Dome C. The 20 points from Fig. 1 have been averaged, and are given by the open symbol. The δ^{18} O data are from ref. 11.

evidence for a longer chronology at Dome C has been presented²⁰. Thus any direct dating of the ice at the bottom of the core would test this hypothesis. The use of the accelerator technique to ¹⁴C date the CO₂ trapped in the ice at the bottom of this core might soon be able to provide such a date.

If the explanation is changing atmospheric circulation, then the pre-Holocene deposition of ¹⁰Be in other geophysical reservoirs, such as marine and lake sediments, should not all show the same effect (meteorology can change the pattern of ¹⁰Be deposition, but cannot increase the total amount deposited). 10Be measurements in these other reservoirs, including an Arctic ice core, are in progress.

If the larger 10Be concentration does reflect increased production before 10,000 BP, then it should be seen worldwide (although not necessarily with the same amplitude). In this case, in addition to the climate implications mentioned earlier, there would be an obvious consequence for 14C dating, as an increased production of this isotope would also be implied. Indeed a combination of ¹⁰Be and ¹⁴C measurements in the same reservoir could be used to calibrate the ¹⁴C scale beyond the presently available tree-ring limit8.

Note that we have not considered the possibility that the increase in 10Be could be caused by a decrease in the geomagnetic field intensity. The argument against this is that at ~6,000 yr BP, when palaeomagnetic data suggest a geomagnetic intensity of approximately only half that of the present² the 10Be concentration is still much less than during the earlier period (although there is some hint in Fig. 2 of an increase at -6,000 yr BP). Thus, while such an effect may be present, it does not seem to be the major cause of the observed increase before 10,000 yr BP. The effect on ¹⁰Be deposition of a varying geomagnetic field is probably minimized near the geomagnetic poles4

While many more and precise measurements will be necessary before the implications of the present results can be appreciated. these initial data fully justify our previous enthusiasm^{2,4} regarding the potential of ¹⁰Be measurements in polar ice cores.

The ice coring programme was supported by Terres Australes et Antarctiques Françaises, NSF (Division of Polar Programs), DGRST and INAG. We thank R. Delmas and M. Pourchet for help in sampling the ice core, J. Jouzel and L. Merlivat for their ¹⁸O/¹⁶O curve, and J. Lestringuez for assistance in preparing BeO samples.

Molecular carbon isotopic evidence for the origin of geothermal hydrocarbons

David J. Des Marais

Ames Research Center, NASA, Moffett Field, California 94035, USA

Jason H. Donchin, Nancy L. Nehring & Alfred H. Truesdell

US Geological Survey, Menlo Park, California 94035, USA

Previous interest in light hydrocarbons from geothermal systems has focused principally on the origin of the methane¹ and the estimation of subsurface temperatures from the carbon isotopic content of coexisting methane and carbon dioxide1-3. Higher molecular weight hydrocarbons were first reported in gases from Yellowstone National Park4, and have since been found to occur commonly in geothermal emanations in the western United States⁵. Isotopic measurements of individual geothermal hydrocarbons are now reported which help to explain the origin of these hydrocarbons. The thermal decomposition of sedimentary or groundwater organic matter is a principal source of hydrocarbons in four geothermal areas in western North America.

Steam from production (water-steam) separators at Cerro Prieto (Baja, California, Mexico) or from steam wells at The Geysers (California) was cooled in a stainless-steel condenser. Steam from fumaroles and hot springs at Steamboat Springs (Nevada) and Yellowstone (Wyoming) was sampled with an inverted funnel held underwater over the steam source. All samples were collected in evacuated 500-cm³ Pyrex flasks containing 100 cm³ of 4 M NaOH solution and having Viton O-ring valve seals. Carbon dioxide and hydrogen suphide readily dissolved in this solution, allowing only the less abundant gases, including the light hydrocarbons, to accumulate in the flask's headspace. This procedure produced negligible amounts of contaminating hydrocarbons. The geothermal hydrocarbons were separated and combusted, and the carbon dioxide product purified and measured using a combined gas chromatographcombustion system^{6,7}. Hydrocarbon identifications were confirmed by comparing the mass spectra obtained by gas chromatography-mass spectrometry with known standard spectra. The carbon isotopic analyses were performed using a modified Nuclide 6-60 RMS isotope mass spectrometer8. The entire procedure was tested using a mixture of hydrocarbons whose individual 13 C contents were known. Accurate δ^{13} C values were obtained which typically had a standard deviation of 0.3%.

The gases studied contained most of the possible saturated hydrocarbon isomers ranging in size from methane to the hexanes5. Benzene was always relatively abundant, but the

abundances of other unsaturated molecules were relatively low and highly variable between sites. The concentration ranges observed in dry gas for the four typically most abundant hydrocarbons are as follows: methane (25–7,000 parts per million (p.p.m.) by volume), ethane (1–200 p.p.m.), propane (10^{-2} –25 p.p.m.) and benzene (10^{-1} to 15 p.p.m.). The balance of abundant headspace gases included nitrogen, hydrogen, helium and argon.

Concerning the origin of the hydrocarbon mixtures, it is useful to evaluate whether the molecules have attained thermodynamic equilibrium with each other. In an equilibrium mixture at 500 K and 20 atm which has relative carbon, hydrogen and oxygen abundances similar to those in these geothermal fluids, methane should be at least 10⁵ times more abundant than all the larger hydrocarbons⁹. The methane to ethane ratios observed in these samples were always less than 600. The abundances of the other larger hydrocarbons were also greatly in excess of the abundances permitted at equilibrium. Therefore, the molecular patterns of these hydrocarbons reflect, at least in part, the kinetically controlled processes responsible for their production.

Two processes have been proposed for the thermal origin of light hydrocarbons in the Earth's crust. First, methane, which is derived either from storage deep in the Earth¹⁰ or synthesized from carbon dioxide and hydrogen¹, might react with itself to produce larger hydrocarbons^{10,11}. Alternatively, higher molecular weight organic matter from sediments or groundwater might thermally decompose to yield light hydrocarbons^{4,11-13}. The hydrocarbons could then escape thermodynamic equilibration, and hence destruction, by migrating to cooler zones in the Earth's crust. If equilibration is incomplete, the products of

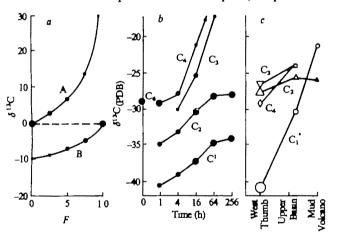

Fig. 1 Relationship between δ^{13} C values of hydrocarbon products and certain parameters which control the products' isotopic composition. Sizes of the data points depict qualitatively the relative molar abundances of the individual hydrocarbon species. a, δ^{13} C values of hypothetical reactant A and product B plotted against F, the fraction of A which has reacted. The curves for A and B have been calculated assuming that the ¹³C in A reacts at a rate which is 1% lower than that of ¹²C. The equations used in these calculations were obtained from ref. 14 b, Isotopic data from the thermal decomposition of hexane Approximately 8-um aliquots of hexane $(8^{13}C_{PDB} = -29)$ were added to 0 4-cm i.d. × 10-cm long Pyrex tubes with a 10-µl syringe. The tubes were evacuated and glass-scaled while immersed in -90 °C bath. The tubes were heated at 500 °C for the various times shown and their contents analysed. Notation adjacent to the curves denotes the compounds as follows: C_1 , methane; C_2 , ethane; C_3 , propane; C_4 , butane; C_9 became (the reactant). c, The δ ¹³ C_{PDS} values of hydrocarbons obtained from three localities in Yellowstone National Park, Wyoming, during October 1980. The δ ¹²C_{FDB} values are plotted against the same y-axis scale used for b. Data point symbols denote hydrocarbons as follows: O, methane (C_1) ; \triangle , ethane (C_2) ; ∇ , propene (C_3) ; \diamondsuit , butane (C_4) ; \square , morture of propene and butane. Sizes of symbols depact qualitatively the relative abundances of the hydrocarbons at the three localities. The abundances of hydrocarbons larger than ethane were insufficient at Mud Volcano to be measured isotopically Both the inferred subsurface temperature and the relative ³He enrichment in the gases increase (see text), whereas hydrocarbon concentrations decrease, from West Thumb to Upper Basin to Mud Volcano The $\delta^{13}C_{PDB}$ values of CO₂ in the West Thumb, Upper Basin and Mud Volcano samples were -0.2 ± 0.2 , -3.4 ± 0.1 and -2.6 ± 0.2 , respectively. For a given sample, $\delta^{13}C_{PDB} = [(^{12}C)^{12}C)_{PDB}, (^{13}C)^{12}C)_{PDB} = 1]]1,000$, where PDB is the PeeDee Belemmite standard

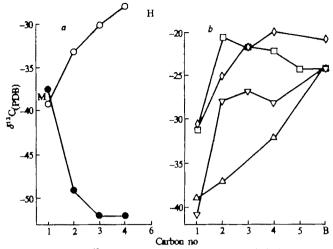

Fig. 2. Plots of δ ¹³C_{TDB} values of individual saturated light hydrocarbons against their carbon number. Numbers on x axis denote carbon number; for example, 1 denotes methane, 2 ethane, and so on. The letter B denotes bearens, a, Results of separate laboratory experiments where hydrocarbons were synthesized by thermal decomposition of hexane at 500 °C for 4 h (O) and a spark in a methane atmosphere (♠). The procedure for the hexane experiment was the same as that described for Fig. 1b. A 2-l Pyrex flask was filled with reagent grade methane (δ ¹³C_{TDB} = −38 6%) to a pressure of 200 mm Hg. The methane was subjected for 1 h to a 2-cm cod spark established between two tungsten electrodes in the flask. The products were extracted from the flask and analysed. The letters H and M identify the δ ¹³C values of the hexane and methane, respectively, at the beginning of the pyrolysis and spark discharge experiments. b, Isotopic abundance of hydrocarbons from four geothermal localities as follows: □, Cerro Prieto, well M-5, sampled January 1979; ⋄, The Geysers, 1979, △, Steamboat Springs, September 1979; ▽, Yellowstone National Park, West Thumb, October 1980

synthesis from methane should differ in their relative intermolecular ¹³C abundances from the products of organic decomposition. It is instructive to discuss next the reasons for such a difference.

Consider a kinetically controlled reaction where chemical compound A is converted to compound B and where the isotope ¹²C in these molecules reacts 1% faster than the ¹³C. The calculated carbon isotopic compositions of A and B are plotted against F in Fig. 1a, where \hat{F} represents the fraction of A (between zero and unity) which is converted to B. The first B which is produced is almost 10% depleted in ¹³C, relative to A. As the abundance of A decreases with increasing F, the ¹³C contents of both A and B must increase to preserve the isotopic mass balance¹⁴. When hexane is thermally decomposed in the laboratory at 500 °C, the 13C contents of the products (see Fig. 1b) change in a similar fashion to that depicted in Fig. 1a. As with the simple system involving A and B, this increase with time in the ¹³C contents of the reacting compounds is derived both from isotopic discrimination which accompanies compounds' production and destruction, and from the requirement that an isotopic mass balance be preserved. Note especially that, in the decomposition process, the lower molecular weight products have lower 13C contents, and that methane has the lowest 13C content of all.

Alternatively, if methane is the carbon source for the thermodynamically unequilibrated synthesis of larger hydrocarbons, these larger hydrocarbons will have lower ¹³C contents than the methane has. For example, this pattern is observed during the formation of hydrocarbons from methane in a spark discharge (Fig. 2a).

The methane in these geothermal samples was consistently more depleted in 13 C than were the associated larger hydrocarbons (Figs 1c, 2b). Thus, the thermal decomposition of organic matter to produce methane and other products is the most important source of these hydrocarbons. This conclusion is supported by our isotopic analyses of coal in drill cuttings from a well in the Cerro Prieto geothermal field. Such coal is a likely carbon source for the light hydrocarbons in the Cerro Prieto steam. The δ^{13} C value of the coal (-24.3) is very similar both to the values of the benzene (-24.0) and hexane (-23.6) in the

geothermal steam and to the values of the benzene (-24.6) and butane (-24.9) produced during vacuum pyrolysis of the coal in the laboratory for 16 h at 400 °C. Furthermore, methane produced from the coal during this laboratory pyrolysis had a δ^{13} C value of -30.0, very similar to the typical value (-31.4) observed for methane from several Cerro Prieto wells.

If the kinetically controlled geothermal decomposition of sedimentary or groundwater organic compounds produces the gaseous hydrocarbons larger than methane, an appreciable portion of the methane itself must be formed by the same process. If some of this methane is not isotopically equilibrated, as the high abundances of the larger hydrocarbons indicate, then such methane is not suitable for use in a geothermometric method which assumes that carbon isotopic equilibrium has been achieved between coexisting methane and carbon dioxide.

Even though thermodynamic equilibrium is not attained, the carbon isotopic contents of methane and carbon dioxide can give apparent equilibrium isotopic temperatures which are higher in hotter subsurface environments3. An example of this correlation can be found in gases from Yellowstone National Park (Fig. 1c). Maximum subsurface aquifer temperatures are inferred by other methods (ref. 15 and unpublished observations) to decrease from Mud Volcano (steam dominated) to Upper Basin (276 °C) to West Thumb (226 °C). The δ ¹³C values of methane and carbon dioxide (Fig. 1c and its legend) yield calculated isotopic temperatures that are highest at Mud Volcano (428 °C), lower at Upper Basin (267 °C) and lowest at West Thumb (142 °C). The ¹³C enrichments in methane with increasing temperature could result from kinetic isotope effects similar to those displayed in Fig. 1b. Note in Fig. 1b that the δ^{13} C of the methane increased with the extent of the hexane pyrolysis; in that experiment, greater pyrolysis was achieved by longer laboratory pyrolysis times. In the case of the Yellowstone and other gases, a more extensive pyrolysis of sediment or groundwater organic matter could similarly be achieved by higher subsurface temperatures. Consequently, the observed 13C enrichment of methane in the hotter subsurface localities might reflect simply a more extensive pyrolysis of sedimentary organic matter, rather than a thermodynamic equilibration between the carbon dioxide and all the methane which is present.

Alternatively, these Yellowstone gases might contain varying proportions of the methane of deep, unknown origins mixed with methane having a shallower subsurface source. The presence of an abundant unequilibrated shallow methane component is indicated by the occurrence of abundant larger hydrocarbons at West Thumb and Upper Basin. The abundances and ¹³C contents of these higher hydrocarbons (Fig. 1c) indicate that their associated methane has a relatively low 13C content and has an abundance which decreases, perhaps by a factor of 10 or more, from West Thumb to Upper Basin to Mud Volcano. Accordingly, the total methane content decreases by a factor of approximately eight from West Thumb to Upper Basin to Mud Volcano. Therefore, the relative proportions of 13Cenriched methane having a different and perhaps deeper origin are successively greater at Upper Basin and Mud Volcano. The presence of successively more concentrated deep components at Upper Basin and Mud Volcano is consistent with the successively greater enrichments of ³He observed at these localities (H. Craig, personal communication).

Additional evidence is being sought to establish more definitively the origin of geothermal methane, including that methane which emanates from the ocean floor 16. Nonetheless, it is now apparent that the ubiquitous presence of organic matter in subsurface continental environments has a key role in the production of geothermal hydrocarbons.

We acknowledge the laboratory assistance of Michael Des Jardin, Loretta McQuaid and Ruth Mack.

Lower Palaeozoic strata on the Pacific Plate of North America

R. Gordon Gastil & Richard H. Miller

Department of Geological Sciences, San Diego State University, San Diego, California 92182, USA

The portion of California (USA) and Baja California (Mexico) lying west of the San Andreas-Gulf of California plate boundary is part of the Pacific Plate, and consists of at least seven distinct lithological terranes (Fig. 1). The only pre-Carboniferous rocks previously identified in any of these terranes are the Precambrian gneiss and plutonic rocks of the San Gabriel Mountains in California (Fig. 1, terrane III). Previous reports of Palaeozoic strata west of the San Andreas Fault in southern California are either erroneous1 or unconfirmed (R. V. Sharp, personal communication). Fossils near El Volcan, Baja California, originally reported as possibly Palaeozoic2, are now recognized to be early Triassic3. Unidentified cup corals and crinoid-like specimens were reported in metamorphosed limestone of the Gabilan Range, central California (Fig. 1, terrane I)4. Unidentified brachiopods and crinoidal debris in the Sierra Pinta of Baja California were assigned to the Carboniferous (Fig. 1, terrane VII; ref. 5). Fossils of Pennsylvanian age were found in a block of limestone and quartzite in a mélange on Isla Cedros. We describe here the first Lower Palaeozoic rocks from the Pacific Plate; this carbonate-quartzite sequence contains Lower Ordovician conodonts and is exposed at San Marcos, 50-km south of the International Border between Tecate and Ensenada (Fig. 1).

The San Marcos section consists of carbonate, quartzite, bedded chert and subordinate slate, and is exposed in a tectonic envelope ~6 km long and 1 km wide. Preliminary mapping suggests that the rocks were thrust over sandstone-slate turbidite deposits presently considered to be of Triassic or Jurassic age (Fig. 1, terrane V). Following tectonic emplacement both the upper and lower plates were folded, weakly metamorphosed and intruded by Cretaceous granite and rhyolite/andesite dykes.

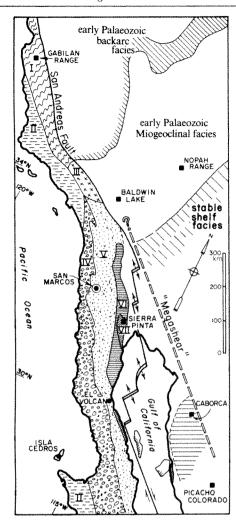

Fig. 1 Index map of seven pre-batholithic basement terranes of the Pacific Plate of western North America. I, Salinian block of highly metamorphosed carbonate-argillite of pre-Cretaceous age. II, Ophiolite, mélange and associated trench facies; Triassic to Cretaceous in age. III, Igneous rocks and gneiss of Precambrian age. IV, Island arc rocks of late Triassic to medial Cretaceous age. V, Flysch facies of early Triassic to late Jurassic age. VI, Amphibolite grade carbonate-quartzite rocks of unknown age. VII, Chertargillite-volcanic rocks of Carboniferous age. Structural features, geographic locations and boundaries of shelf, miogeoclinal and back-arc facies are indicated. Conodont-bearing rocks occur at San Marcos within terrane V, latitude 116°25′33″W, longitude 32°09′46″N. Samples were collected on a saddle of a north-west trending ridge at an elevation of ~750 metres, Hoja I11D82, Francisco Zarco quadrangle, Baja California, Mexico.

Lithological specimens ranging from reddish-brown weathered, dark-grey, fine- to medium-grained dolomitic limestone to very dark-grey, fine-grained dolomitic limestone were collected from limited exposures on brush-covered slopes. Six samples, weighing 535-1,025 g, were dissolved in 10-12% acetic acid. Fossils were recovered from three samples, but only one (VS3, 797 g) contained abundant conodonts (~250) and other fossils, including inarticulate brachiopod fragments, small gastropod steinkerns, pelmatozoan columnals and sponge? spicules. Only the conodonts are preserved well enough for more specific identification.

Most of the conodonts are broken, etched, compressed and have been thermally altered to a dark brown or black (CAI index of 5-6)⁷. Despite poor preservation seven multi-element taxa and four other morphological types were identified (Table 1, Fig. 2). With the exception of fragments tentatively identified as Eoplacognathus? sp., other species are characteristic of the Prioniodus evae/Oepikodus evae Biozone of early Ordovician (medial Arenigian) age as recognized in the British Isles^{8.9}. These taxa and Scolopodus cornutiformis suggest a correlation with early Ordovician Faunas D/E of late Canadian age as described for the US mid-continent¹⁰. Therefore the conodonts provide evidence of close correlation with European biozones and series, but provide only tentative correlation with North American mid-continent taxa.

These taxa are representative of two Ordovician biogeographic provinces. Six species, which represent most of the recovered specimens, are diagnostic of the North Atlantic province^{11,12}; two species are diagnostic of the North American mid-continent province (Table 1)^{11,12}. The diversity and abundance of the specimens indicate that these rocks formed in a North Atlantic province setting. In North America, rocks containing medial Arenigian conodonts of this province have been reported from the northern Appalachians, the Marathon region in Texas, and from the Cordilleran region of Canada and the United States¹². Medial Arenigian rocks outside North America that contain conodonts of this province have been reported from central, western and southern Europe, south-east Asia, Australia and Argentina^{9,11,12}. The distribution of these localities on Ordovician palaeogeographic maps 13 indicates that all occur at least 10-15° north or south of the Ordovician palaeoequator. Thus the conodont taxa, the abundance of specimens in the dissolved sample, and the lithology indicate the rocks were deposited on a continental shelf (miogeocline) in subtropical to temperate palaeoclimates.

These Lower Palaeozoic miogeoclinal rocks are isolated from other known outcrops of carbonate rocks, and lithological relationships with other sections are very tentative. The San Marcos exposures are 70 km south-west of strongly metamorphosed quartzite-carbonate rocks of unknown age found in the desert

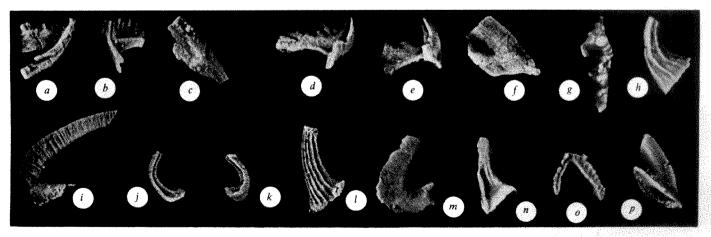

Fig. 2 Conodonts from sample VS3. All specimens are from SDSU location number 3236, Allison Center, Department of Geological Sciences, Specimens i. j. k. l., m, and p are magnified by ~22 diameters, all others by ~35 diameters. a, b, c, Prioniodus (Oepikodus) evae (Lindström), oepikodiform, prioniodiform and oistodiform elements; d, e, f, Prioniodus (Periodon) flabellum (Lindström), ramiform, ramiform and oistodiform elements; g, Eoplacognathus? sp.; h, Walliserodus ethingtoni? (Fåhraeus); i, Drepanodus arcuatus Pander, j, k, Protopanderodus varicostatus Sweet & Bergström; l, Scolopodus cornutiformis Branson & Mehl; m, Cordylodus? sp.; m, scandodiform element; o, trichonodelliform element; p, oistodiform element.

ranges west of the plate boundary (Fig. 1, terrane VI). On the east side of the plate boundary, in northwestern Sonora near Caborca (Fig. 1), is a relatively unmetamorphosed sequence of miogeoclinal rocks of late Precambrian and Cambrian ages^{14,15} that was correlated with the miogeoclinal succession of the Nopah Range in the southern Great Basin of California 16. No Ordovician rocks were recognized in the Caborca section, but Upper Ordovician strata of deep water facies occur 200 km to the south at Picacho Colorado (Fig. 1)^{17,18}. Another possibly related section of carbonate-quartzite rocks, near Baldwin Lake in the San Bernardino Mountains, California (Fig. 1), was also correlated with Cambrian and older rocks in the Nopah Range^{19,20}.

Despite difficulties in establishing lithological relationships, this well documented section of Ordovician miogeoclinal rocks west of the plate boundary is important in formulating interpretations of Palaeozoic and younger tectonic history of the southwestern part of the Cordilleran geocline. Geologists have long speculated about the possible truncation and/or displacement of geocline rocks in areas that now represent the Mojave desert, Baja California, and northern Sonora. Anderson and Silver²¹ suggested that some of these rocks, such as those represented by the Caborca sequence, were transported southeastwards some 700 km along a left-lateral 'megashear', perhaps in medial Jurassic time. Others²² have suggested that displacement of the miogeoclinal rocks was to the north-west. Whether or not the Caborca rocks were once adjacent to the southern Great Basin/Mojave Desert, the carbonate-quartzite terrane of the desert ranges (Fig. 1, terrane VI) is now separated from the western edge of the Caborca terrane by more than 300 km across the northern Gulf of California rhombochasm. The sense of motion and distance agree with independent evidence for plate boundary separation across the Gulf^{23,24} Palaeomagnetic studies, however, suggest that northern Baja California was much further south relative to the rest of North America at the time of Cretaceous granitic intrusion^{25,26} Resolution of these palaeogeographic arguments is not yet possible. The Lower Ordovician carbonate-quartzite rocks of San Marcos, Baja California must be taken into account in reconstruction of displaced terranes along the western margin of North America during the past 100 Myr.

We thank E. Frost for helpful suggestions and discussions and G. Peterson for editorial suggestions. Grants from the National Geographic Society and San Diego State University provided funds for some of this research.

Musth in the African elephant, Loxodonta africana

Joyce H. Poole* & Cynthia J. Moss†

*Sub-Department of Animal Behaviour, University of Cambridge, High Street, Madingley, Cambridge CB3 8AA, UK †African Wildlife Leadership Foundation, PO Box 48177, Nairobi, Kenva

The phenomenon of musth in male Asian elephants, Elephas maximus, has long been recognized1. Musth, which has been likened to rutting behaviour in ungulates2, refers to a set of physical and behavioural characteristics displayed periodically by adult male elephants. The most obvious manifestations are a sharp rise in aggressive behaviour, copious secretions from and enlargement of the temporal glands, and the continuous discharge of urine3. It has been speculated that a similar phenomenon occurs in males of the African genus, Loxodonta africana, but most workers have concluded that it does not exist⁴⁻⁷. Here we show that musth does occur in the African elephant and that its manifestations are similar to those in the Asian elephant.

Musth, well documented in the domestic and wild Asian elephant^{2,3,8,9}, is confined to post-pubertal males, is accompanied by high testosterone levels8, and usually lasts for 2-3 months, with a range of several weeks to 9 months³. Individual males tend to come into musth annually or biannually, but unlike the seasonal rutting of most ungulates, must periods are unsynchronized and occur throughout the year, with usually only one male in musth at a time⁹. In wild populations males in musth show a positive association with female herds9.

The most important indicator of musth in the Asian elephant is the onset of secretion from the temporal glands, which, with rare exceptions, occurs only in males in this condition^{2,3}. In the African genus, however, temporal gland secretions of short duration often occur in both immature and mature elephants of both sexes. Previous studies have shown that there is no relationship between such secretions and sexual activity^{4,6}. It is perhaps for this reason that many workers have concluded that musth does not occur in the African elephant.

The discussion of musth has been further confused by the incorrect use of the term, which in Africa is often applied to temporal gland secretions alone, rather than to the behavioural and physiological syndrome originally intended in Asia. Thus males, females and juveniles are often referred to as 'having musth' when they are observed with temporal gland secretions. To avoid such confusion we use the term 'musth' in its original sense and the term 'temporin' as used by Sikes7 to refer to secretions from the temporal glands.

We have made continuous observations on male African elephants since September 1975, as part of a long-term study of the elephant population in Amboseli National Park, Kenya. The Park covers an area of 390 km² and consists of semi-arid wooded, bushed and open grassland interspersed with a series of permanent swamps. The surrounding area, making up an ecosystem of ~3,500 km², is semi-arid savannah in which water availability is highly seasonal¹⁰. This ecosystem is inhabited by a free-ranging population of elephants numbering 580 individuals, of which ~ 155 are adult males. All adults of both sexes and most juveniles are known individually.

During the 5 years of data collection, we observed a pattern of characteristics displayed by the older males (those estimated as being > 30 years) in the population. We first noticed individuals with continuously dripping urine, which was accompanied by a strong odour and greenish coloration to the proximal part of the penis and the distal part of the sheath. We referred to this as the 'green penis syndrome' or 'GP'. GP in bulls was recorded whenever it was observed together with other accompanying characteristics, which included a pronounced enlargement of and continuous and copious secretions from the temporal

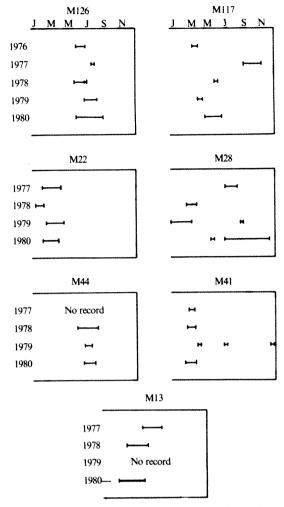

Fig. 1 The minimum duration and degree of periodicity of musth in seven males for the years 1976-1980. The vertical lines indicate the first and last days that the bull was observed to be in musth.

glands, an increase in aggression, and a positive association with female herds. The occurrence of these characteristics, their frequency, duration and association are examined here for seven large bulls in the population for which we have at least 3 years of data.

The coincidence of copious temporin and GP was pronounced in the seven bulls ($\chi^2 = 84.58$, d.f. = 1, P < 0.001). There was also a positive correlation between the occurrence of the secretion of both temporin and urine (GP) and the amount of aggressive behaviour shown by these bulls. For each of the seven bulls, we examined the rate of aggressive interactions during secreting and non-secreting periods and found a significant increase in aggression among all bulls who were secreting (Wilcoxon matched-pairs test: T = 0, n = 7, P < 0.01). In addition there was a positive correlation between GP and association with female herds. When the bulls were seen with females, GP was observed in 93% of the sightings (n = 123), whereas when they were in groups of bulls alone, GP was observed in only 11% of the sightings (n = 83). GP is thus strongly correlated with the association of males with females ($\chi^2 = 141.29$, d.f. = 2, P <

An examination of the records of frequency and duration of the described characteristics in the seven bulls reveals an individual periodicity which is variable (Fig. 1). Five of the bulls exhibited the characteristics once each year, one twice (M28), and another three times (M41). For some males (M126, M22, M44 and M13), the onset of the phenomenon is fairly consistent from one year to the next, whereas for others (M117, M28 and M41) there is no clear pattern. For all bulls observed exhibiting the characteristics at some point in the study (n = 18), the range of duration was from 1 to 103 days.

The similarity between the physical and behavioural characteristics shown periodically by African male elephants and those described as musth for Asian males leads us to conclude that musth does occur in the African genus. Several factors have probably contributed to the fact that musth has been overlooked in the African elephant. In wild populations the presence of temporin in both sexes confused the issue and without long-term records on individually known males musth was not detected. Among captive African males, there are few individuals > 30 years old, because large adults are difficult to handle, thus most would not be old enough to come into musth.

Recent evidence from our study reveals that bulls in musth become sexually more active and achieve a higher dominance rank than at other times, and that musth males are significantly more often in consort relations with oestrous females than are non-musth males. Thus musth may play a part in an individual's reproductive success. Further investigations by J.H.P. are examining the behavioural and ecological factors that determine the age and rank at which males initially come into musth, the timing and duration of musth periods, and how these considerations relate to reproductive success.

We thank H. Croze, A. Hill, R. Malpas and D. Western for reading the manuscript and making helpful suggestions, the Wildlife Conservation and Management Department and Office of the President of Kenya for making the research possible, and wardens Joe Kioko and Bob Oguya for their assistance in Amboseli. Financial support was provided by the African Wildlife Leadership Foundation, the New York Zoological Society and Smith College.

Formation of ACh receptor clusters induced by positively charged latex beads

H. Benjamin Peng, Ping-Chin Cheng & Paul W. Luther

Department of Anatomy, University of Illinois College of Medicine, PO Box 6998, Chicago, Illinois 60680, USA

An early event in the formation of neuromuscular junctions in tissue cultures of neurones and muscle cells is an accumulation of acetylcholine receptors (AChRs) in the postsynaptic membrane 1-5. As well as direct neuronal contact, AChR cluster formation can also be induced by certain soluble factors extracted or released from neurones⁶⁻⁸, by isolated basal lamina material9 or by a piece of degenerating nerve10. These experiments suggest that certain 'trophic factors' released by the neurones or the neuronal cell surface itself may cause the receptor clustering. On the other hand, stable AChR clusters are also present in pure muscle cultures without neuronal influence 1,10-13, which indicates that an interaction between the muscle and an exogenous cue existing on the substrate or in the medium may be sufficient to trigger the mechanism for the clustering of AChRs in the muscle. Here we report the effect of charged latex beads on the formation of AChR clusters in cultured muscle cells. Our results clearly indicate that AChR clusters form specifically at the contacts with polylysine-coated beads. Furthermore, these beads suppressed clusters that formed in the non-contact area before the introduction of the heads.

Table 1 Association of AChR clusters with beads

	Days of		Α	ChR clu	sters (%)*		
	bead-muscle		Top/	edge	Bot	tom	No. of clusters	No. of cells
Experiment	co-culture	Beads	+		+	****	scored	scored

\boldsymbol{B}	6	Polylysine	94	4	2	0	176	21
		Uncoated	4	60	0	36	109	13

Experiments A and B were from two separate batches of muscle cultures. To minimize any influence on the formation of AChR clusters by an interaction between neighbouring muscle cells or by factor(s) released by the cells, we plated the cells at extremely low density: 20-30 cells per 18×18 mm cover-glass on average. Usually all clusters located on each cell, including its top, edge and bottom, and all cells in each culture were scored. Polylysine beads were prepared from uncoated polystyrene latex beads. Polycarboxylate beads were obtained directly from Polysciences (surface charge, 0.46 mequiv. COO⁻ per g polymer).

* AChR clusters located on the top or the edge of the cell, or on the bottom of the cell as judged by the focusing level of the microscope. Each cluster, after fluorescence observation, was examined with phase-contrast optics to assess its association with beads by simply turning on the transmitted light illuminator without moving the specimen. +, Cluster associated with beads; -, cluster not associated with beads.

Muscle cells isolated from Xenopus laevis embryos were cultured on coverslips in Steinberg's solution: 60 mM NaCl, 0.7 mM KCl, 0.4 mM Ca(NO₃)₂, 0.8 mM MgSO₄, 10 mM HEPES, pH 7.4, supplemented with 10% L-15 (Leibovitz) medium and 1% fetal bovine serum^{1,14}. Positively charged beads were made by incubating 1-µm polystyrene latex beads with 1 mg ml⁻¹ poly-L-lysine (molecular weight (MW) 1,000-4,000; Sigma), dissolved either in distilled water or in phosphate-buffered saline (PBS), overnight at 4 °C, then washing thoroughly with distilled water or PBS. Uncoated beads were used as control. Negatively charged 0.9-µm polycarboxylated beads (Polysciences) were also used. Beads of each type were suspended in culture medium and applied to separate muscle cultures. After incubation for 10-30 min, excess beads were washed off and the cultures transferred to fresh medium. All three kinds of beads brought into contact with the cells adhered strongly to them, even when subjected to repeated washing, as shown in Fig. 1. At the stage required, the cultures were labelled with tetramethyl rhodamine-conjugated α-bungarotoxin (R-BTX), which binds specifically to AChRs 1,15,16. After washing and fixing with 95% ethanol at -20 °C, the culture was mounted on a slide with a mixture of polyvinyl alcohol and glycerol and examined using a Leitz Orthoplan microscope equipped with an epifluorescence illuminator. The location of fluorescent R-BTX-bound AChR clusters was correlated with the phasecontrast image of the cell and the beads by switching between epifluorescence and phase-contrast optics. Fluorescence of AChR clusters was completely suppressed when the cultures were first incubated with native α -BTX then with R-BTX.

In 1-week control cultures (without beads), an average of eight AChR clusters (0.5 µm to >10 µm) per cell were observed. Most of these (60-80%) were observed on the top or along the edge of the cell but 20-40% were also observed on the bottom of the cell. A class of large clusters similar to the one shown in Fig. 2a was observed in $\sim 50\%$ of the cells. These large clusters consisted of many smaller AChR aggregates and were found predominantly on the bottom of the cell, in contact with the substrate. In cultures treated for 1-2 days with uncoated or polycarboxylated beads, the distribution of AChR clusters was similar to that of the control. There was no significant association between the beads and the AChR clusters (Fig. 2a-d, Table 1A). About 45% of these cultured cells had large bottomlocated clusters (see Fig. 2a). However, in cultures treated with polylysine-coated beads for 1-2 days, almost all AChR clusters observed by R-BTX fluorescence were associated with single beads or small aggregates of beads which seemed to be in contact with the muscle cell. The results of one set of experiments are given in Table 1A and representative examples shown in Fig. 2e-h. It is obvious from Table 1A and B that almost all AChR

clusters in polylysine bead-treated cultures are located on the top or the edge of the cell where the beads come into contact with the cell. The absence of AChR clusters on the bottom of the cell corresponds well with the absence of beads in that area, from which they are excluded by the narrow gap between the cell and the substrate. This is in contrast to the control cultures and those treated with uncoated or polycarboxylated beads which usually show a substantial number of bottom clusters, particularly the large type illustrated in Fig. 2a. This indicates that the polylysine-coated beads not only induce the formation of new AChR clusters at bead-muscle contacts but also suppress the pre-existing clusters in non-contact areas.

In these experiments we used a dilute bead concentration to reduce the possibility of random association of beads with existing receptor clusters. As the size and shape of the muscle cells are heterogeneous, the number of bead-muscle contacts per cell also shows a wide variation. However, from Fig. 3 it is clear that the number of bead-muscle contacts is positively correlated with the number of associated AChR clusters, which further supports the notion that the beads induce formation of new clusters. There were $\sim 30\%$ apparent bead-muscle contacts not associated with receptor clusters. Clusters formed around single beads were discrete and closely apposed to the beads (Fig. 2e-h) whereas those formed under an aggregate of beads were usually composed of several discrete sub-clusters (Figs 2g-h and 4a-b).

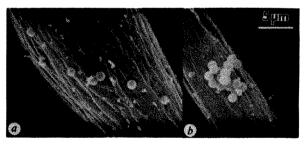

Fig. 1 Scanning electron micrograph of the association of latex beads with muscle cells. Poly-L-lysine-coated beads were used in this experiment. Two days after the bead-muscle co-culture, the cells were fixed using a mixture of 3% glutaraldehyde and 4% tannic acid, followed by post-fixation with 1% OsO₄. The preparation was then dehydrated in a graduated ethanol series, critical-point dried through CO₂, coated with palladium-platinum on a sputter coater and viewed with a JEOL 35C scanning electron microscope at an accelerating voltage of 25 kV. The attachment of single beads (a) or small aggregates of beads (b) to muscle cells can be clearly seen. This bead-muscle association is obviously strong enough to withstand the various medium changes during specimen preparation.

Fig. 2 Relationship between the AChR clusters and the bead-muscle contacts. The cells were treated with latex beads for various time periods and the location of AChR clusters assayed by labelling with R-BTX and fluorescence microscopy after fixation with cold 95% ethanol. A Leitz Orthoplan microscope equipped with a ×40 phase-contrast objective (n.a. 1.3) and epifluorescence illuminator with filter cube N2.1 was used. a, c, e and g are fluorescence micrographs; b, d, f and h the corresponding phasecontrast images. a, b, Cells were treated with polycarboxylated beads for 2 days. In a, the focus was on the bottom of the cell in contact with the substrate. In this area, the beads are excluded. A large AChR cluster, composed of many smaller subunits, is seen. This type of cluster was observed in about 50% of the cultures treated with polycarboxylated beads or uncoated beads as well as in control cultures without beads; b focuses on the centre of the cell. c, d, Cells were treated with uncoated beads for 2 days; c focuses on the AChR clusters on the top of the cell where the beads are also located (d). It is clear that the AChR clusters do not bear any

particular relationship to the beads. e-h, Cells were treated with poly-L-lysine-coated beads for 1 day (e, f) and 2 days (g, h). In e, most of the AChR clusters located on the top and the edge of the cell are found precisely at the bead-muscle contacts. The numbers denote the correspondence in location between the fluorescence (e) and phase-contrast (f) images obtained using identical focus. Beads which fall on the glass substrate are not associated with fluorescence. In g and h, a larger number of bead-muscle contacts is also associated with a larger number of bead-associated AChR clusters. Both single beads and small aggregates of beads (nos 5, 8-10) can cause AChR cluster formation.

Clusters formed shortly after the beads came into contact with the muscle cell; even after 6 h of bead-muscle co-culture, we detected 65% of the clusters already associated with beads. Table 1B summarizes the results of a time study using polylysine-coated and uncoated beads. It shows that almost a full effect of the polylysine-coated beads was evident after only 1 day of bead-muscle co-culture. The receptor clusters formed at

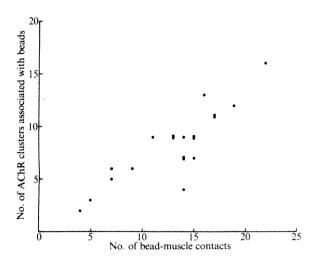

Fig. 3 Correlation between the number of AChR clusters associated with polylysine-coated beads and the number of beadmuscle contacts on individual cells. Each of the 20 cells scored is represented by a black circle. The number of bead-associated AChR clusters increases approximately linearly with the number of bead-muscle contacts.

the contacts seemed to be stable for at least the 6 days of this study. No R-BTX fluorescence was ever detected when beads came into contact with the culture substrate (Fig. 2e-h) or non-muscle cells (Fig. 4c-d).

These results indicate that the effect of polylysine-coated beads is very similar to that of nerve innervation. During the formation of a neuromuscular synapse in vitro, the nerve induces AChR cluster formation at the innervated site and suppresses pre-existing clusters in non-innervated areas². Our data indicate that a localized interaction between the muscle surface and polylysine-coated beads can trigger the mechanism for the formation of AChR clusters. This process may be mediated by the positive charge on the surface of the beads, a chemical interaction between the polylysine molecules and the cell surface, or even certain factor(s) from the culture medium adsorbed onto the positively charged beads. Further experiments are being done to investigate these possibilities.

We have repeated the above experiments using larger $(6 \mu m)$ polylysine-coated beads, which make larger contacts with the muscle cells and the resultant AChR clusters are also larger, but each cluster is still located within the confines of the contact area. This further indicates that a local cell-bead interaction triggers the clustering of AChRs. Although latex beads are known to be phagocytosed by certain cultured cells, for example, macrophages¹⁷, recent electron microscopic (EM) studies (H.B.P., P.-C.C. and P.W.L., in preparation) give no evidence of this in cultured muscle cells. Also, in our scanning electron micrographs (Fig. 1), beads were always seen on the cell surface and no intermediate stages of phagocytosis were observed. We have found that the bead-induced AChR clusters are accompanied by membrane-associated cytoplasmic densities in thin sections and clusters of large intramembranous particles in freeze-fracture replicas, which are also characteristic of spontaneously formed AChR clusters'. Closely related to our

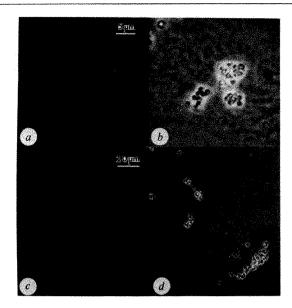

Fig. 4 a, b, AChR clusters formed at the bead-muscle contacts shown at a higher magnification than in Fig. 2. The small subunits in a cluster associated with multiple beads are obvious. c, d, The contact area between the bead and the non-muscle cell is not associated with any R-BTX fluorescence. a, c, R-BTX fluorescent images; b, d, phase-contrast images. These two cells were from the same culture and thus received the same treatment.

observation is the finding18 that neurites in cell cultures of rat cerebellum can form apparent presynaptic elements, including dense material and accumulation of synaptic vesicles, at their contacts with positively charged Sepharose beads. Thus a surface interaction between the neurite and the target cell may trigger the formation and registration of both the pre- and postsynaptic specialization during the initial stages of synaptogenesis.

Creation of direction selectivity in adult strobe-reared cats

Tatiana Pasternak*, J. Anthony Movshon† & William H. Merigan‡

*Center for Visual Science and ‡Department of Ophthalmology, University of Rochester, Rochester, New York 14627, USA †Department of Psychology, New York University, New York 10003, USA

Animals raised in a stroboscopically illuminated environment have deficits in several visual functions, including visuo-motor integration¹, discrimination learning² and spatial contrast sensitivity3. Moreover, recordings from the visual pathways of strobe-reared animals show severe functional abnormalities, including greatly reduced selectivity for orientation and for directional motion in neurones of the visual cortex and superior colliculus⁴⁻⁹. Subsequent normal visual experience improves cortical orientation selectivity, but does not alter the neural deficit in direction selectivity6.7. As the motion-analysing capacities of strobe-reared animals have not been studied, we examined the ability of strobe-reared cats to discriminate stationary from moving patterns. We report here that the cats detected motion in the direction for which they had originally been trained much better than motion in other directions. In recordings from striate cortex in these animals, orientation and direction-selective neurones were encountered with a frequency much higher than that seen in strobe-reared cats not trained in motion discrimination, and comparable with that in normal cats. Moreover, the distribution of the preferred directions of these neurones was sharply biased towards the direction first seen in training. We conclude that there exists an extended period of cortical plasticity in strobe-reared animals, which, in contrast to that previously reported6, includes plasticity of direction selectivity.

We carried out behavioural tests on five cats; two were reared from birth to the age of at least 14 months in a room illuminated for 12 h each day with a stroboscopic flash of 3 µs duration at a rate of 0.67 Hz, and two were raised normally. One was raised in an environment intermittently illuminated with a flash of light 750 ms in duration at 0.67 Hz; the luminance of this flash was adjusted so that normal adult cats could resolve fine detail in this illumination as well as they could in the stroboscopic illumination. Behavioural testing began no less than 4 months after the animals were removed from their rearing environment.

The cats were trained to discriminate stationary from moving random-dot patterns using a forced-choice procedure based on that developed by Berkley¹⁰; our modification of this method has been described in detail elsewhere¹¹. The animals were trained to indicate which stimulus moved by pressing with their noses on one of two transparent panels through which they viewed the stimuli. Each stimulus consisted of a sheet of 400 bright dots, each 0.5° in diameter, on a dark background; the sheet subtended 22° at a viewing distance of 30 cm. Most of the energy in the pattern was concentrated at spatial frequencies below 1c/deg, which are visible to strobe-reared cats¹

During the initial training, the stimulus always moved to the right at 44° s⁻¹; after 12–30 days, with 200 trials per day, all cats satisfactorily discriminated between this stimulus and the stationary one. Strobe-reared cats were no slower in acquiring this discrimination than control cats. We next measured the lowest detectable speed using the method of constant stimuli. In each session five speeds were chosen to bracket threshold, and were presented randomly in blocks of five trials. Threshold was taken as the point at which resulting psychometric functions produced 75% correct performance.

The motion thresholds of the control cats improved over several months of testing from an initial value between 8 and $11^{\circ} \, s^{-1}$ to an asymptotic value between 0.9 and $1.5^{\circ} \, s^{-1}$. The initial thresholds of the strobe-reared cats were high in comparison (between 17 and 25° s⁻¹); after prolonged testing (~8 months during which the animals received ~18 h of exposure to moving dots) the thresholds stabilized near 3° s⁻¹, 2-3 times higher than those of control cats.

In all tests described above, rightward motion was used. We next examined the transfer of this training to other directions.

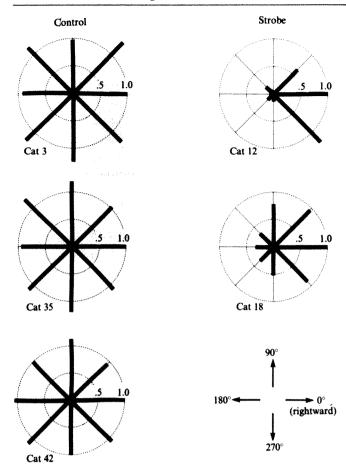

Fig. 1 Polar diagrams showing the speed sensitivity of control and strobe-reared cats to motion in eight directions. Each bar plots the inverse of the speed required for 75% correct performance on a two-choice discrimination between a stationary and a moving random-dot field. The bars in each case are normalized so that sensitivity to rightward motion is given a value of 1. Data are shown for two normal cats (3 and 35), one cat raised in an intermittently illuminated environment (42, see text) and two cats raised in a stroboscopically illuminated environment (12 and 18). Their actual thresholds for rightward motion were 0.9, 1.2, 2.0, 2.0 and 4.4° s⁻¹, respectively. A repeated measures analysis of variance showed that none of the control animals was significantly better at motion discrimination in any particular direction (P > 0.05). However, both strobe cats were significantly more sensitive to motion within 45° of rightward than they were to other directions (P < 0.05).

On each day, the threshold for one direction was tested. Over several days, an irregular sequence of eight directions, evenly spaced around 360°, was presented. Figure 1 shows the sensitivity of each of the five cats to motion as a function of the direction tested. In each polar diagram, the length of bar represents the inverse of the speed threshold for a particular direction of motion; the values are normalized with respect to the cat's sensitivity to rightward motion, which is given a value of 1. The control cats had a similar sensitivity in all test directions, whereas the strobe-reared animals were much more sensitive to rightward motion than they were to motion in directions more than 45° from this, the initial direction of training. The high thresholds for directions for which no training had been given remained stable over 7 months of further training, in which stimuli moved upwards, downwards and to the left, and did not improve as the initial high thresholds for rightward motion had done earlier. Note also that this deficit did not represent a simple failure to generalize from one direction to another, as the strobe-reared cats were capable of discriminating motion in all directions, yielding stable psychometric functions of normal slope; it was simply that when tested with rightward motion, they required only low stimulus speeds compared with those required for detection of motion in other directions.

The peculiar sensitivity of these strobe-reared cats to rightward motion led us to examine the orientation and direction selectivity of striate cortical units, using methods described elsewhere¹². Control data were obtained from six other adult strobe-reared cats that had received comparable periods of normal visual experience but had not been trained to discriminate motion, and from seven normally reared adult cats. Animals were prepared for electrophysiology using barbiturate anaesthesia (Pentothal); they were then paralysed with Flaxedil and artificially ventilated with 80% N₂O in O₂ and CO₂. Their corneas were covered with contact lenses containing 4-mm artificial pupils, and supplementary lenses were used to focus the eyes on a screen 72 cm distant. Single cortical units were isolated using tungsten microelectrodes, and their activity amplified and displayed. We studied the properties of 88 and 87 units in the two strobe-reared animals, in each case drawing our samples equally from long medially directed penetrations in the two hemispheres. For comparison, we made recordings of 183 units from normal cats. All units were histologically verified to lie in area 17.

Receptive fields were mapped on a tangent screen using bars, edges and spots of light, and classified according to the scheme of Hubel and Wiesel¹³ as modified by Blakemore and Van Sluyters¹⁴. No quantitative response measures were used but we paid careful attention to the orientation and direction selectivity of each neurone. Cells were classified as orientation selective (OS), orientation biased (OB), or not oriented (NO) using criteria described elsewhere¹⁴. Cells were direction selective (DS) if they responded markedly better to one of the two directions of motion of an optimally oriented stimulus, direction biased (DB) if they responded discriminably better to one direction than the other, and not directional (ND) if there was no difference in the responses to the two directions.

The data from the two cats trained to discriminate motion were generally similar to those from normal cats, and differed markedly from those of other strobe-reared animals studied by us and others^{4-7,15}. Table 1 lists the proportions of OS and OB neurones in the three groups of cats, and the proportions of those in each of the three classes of direction sensitivity. While strobe-reared cats given a period of normal visual experience showed abnormally low proportions of orientation- and direction-sensitive neurones (62% and 35% respectively), both motion-trained animals had roughly normal proportions of selective cells: in our sample, 93% of neurones were classified as OS or OB; of these 65% were either DS or DB. By comparison, 99% of neurones in normal cats were orientation sensitive, and 74% of these were DS or DB.

While cells preferring all orientations were direction selective in the motion-trained cats, there was a marked bias in the

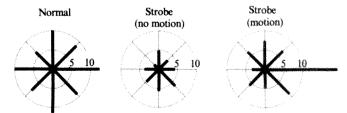

Fig. 2 Polar histograms showing the distributions of direction preference for cortical neurones showing direction sensitivity in three groups of cats: normal; strobe-reared but not motion-trained; and strobe-reared and trained in motion discrimination (cats 12 and 18 from Fig. 1). The histograms show the percentage of the total population of cortical neurones in each group that preferred directions in the ranges indicated. The results are based on totals of 192 cells from seven normal cats, 183 from six strobe-reared cats not trained in motion discrimination, and 175 cells from two strobe-reared cats trained in motion discrimination using rightward motion. The distributions of direction preference were similar in the two motion-trained cats: 21% of all cells in cat 18 and 17.5% in cat 12 preferred rightward motion, whereas only 5% of cells in cat 18 and 2% in cat 12 responded preferentially to leftward

Table 1 Proportion of orientation- and direction-sensitive neurones

		All	cells	OS and OB cells		
Experimental group	Cells	% OS	%ОВ	%DS	%DB	%ND
Normal cats	192	90	9	42	32	26
Strobe cats (not motion- trained)	183	40	22	12	23	65
Strobe cats (motion- trained)	175	91	2	32	33	35

distribution of direction selectivity. This is shown in Fig. 2, which gives the direction preferences of cortical units from the three groups of cats. In the two motion-trained cats, 59 units had preferred orientations within 22.5° of vertical: of these 40 (68%) showed a direction preference, with 34 of the 40 (85%) preferring movement to the right and only six (15%) preferring movement to the left. In these cats, 89 cells were both direction selective and preferred orientations within 67.5° of vertical; 62 of these (70%) preferred the direction having a rightward component; only 27 (30%) preferred motion with a leftward component. By comparison, among the 70 direction-sensitive cells preferring orientations within 67.5° of horizontal, 36 (51%) preferred motion with an upward component and 34 (49%) preferred motion with a downward component. Neither the direction-sensitive neurones from normal cats nor the few such neurones from strobe-reared cats not motion-trained showed any significant anisotropy in the distributions of their preferred directions.

Thus in two adult strobe-reared cats trained extensively to discriminate motion, we found both recovery of motion detection performance and recovery of cortical direction selectivity. This confirms previous suggestions^{6,16,17} that in strobe- and dark-reared cats it is possible to demonstrate a period of cortical plasticity that extends beyond the traditional 'sensitive period' for cortical development. Our results are unusual in that they suggest that this extended plasticity, which does not normally include direction selectivity, may do so if animals are preferentially exposed to moving stimuli.

Also interesting is our finding of a bias towards the initially trained direction in both the psychophysical motion sensitivity and the directional preferences of cortical neurones in these cats. Cortical direction selectivity can be biased in young kittens exposed to a restricted range of directions of motion 18-20, but these changes have only been shown to occur during a restricted period in early life that ends well before the period of sensitivity to the effects of monocular occlusion^{21,22}. Our data show that a qualitatively and quantitatively similar effect may be seen in adult strobe-reared cats exposed to a motion-biased environment. The magnitude of the effects is similar to those reported elsewhere for young animals, which is surprising in view of the fact that our animals received 4 months of normal vision before training and received 12 h per day of concurrent unbiased visual stimulation. In our experiments the cats were required to attend to the moving stimuli to obtain behavioural reward, which may have rendered those stimuli in some way more potent modifiers of cortical function.

Neuronal precursor cells in the chick neural tube express neurofilament proteins

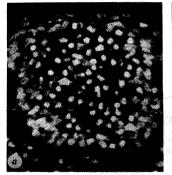

S. J. Tapscott, G. S. Bennett & H. Holtzer

Department of Anatomy, University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA

Biochemical and immunological differences have been demonstrated in intermediate-sized (or 10-nm) filaments (IFs) from a variety of cell types (for reviews see refs 1-4). Neurofilaments, the IFs of neurones (NIF), are composed of three proteins that differ from those of non-neuronal IFs 5-12. Yet, in the 2-day-old chick neural tube, virtually all the replicating neuroepithelial cells, the precursor population to spinal cord neurones and glia. contain IF proteins that are immunologically and biochemically identical to the major IF protein present in chick fibroblasts, FIF protein (vimentin¹³, decamin¹⁴); they contain neither NIF proteins nor the IF proteins characteristic of astrocytes (glial fibrillarv acidic protein 15,16), muscle cells (desmin 17, skeletin 18) and epithelial cells (prekeratin 19,20)21. As the neuronal progeny of these cells mature, they synthesize NIF proteins and cease expression of FIF protein 10,21. In this study, we have used antisera against different IF proteins to show that, at a time when neurones are withdrawing from the cell cycle, NIF proteins are present in a small percentage of replicating neuroepithelial cells, probably appearing during the terminal cell cycle of the neuronal precursor; and that for a brief period the postmitotic neuroblast expresses both NIF and FIF proteins.

Our findings are based on immunofluorescent localization of IF proteins using previously characterized antisera against FIF protein^{22,23}, the 180,000-molecular weight (MW)^{10,21} and 70,000-MW²¹ NIF proteins, and IF proteins characteristic of astrocytes²¹ and muscle cells^{23,24}. Cryostat sections were taken primarily from the brachial region of the embryonic chick neural tube, although more rostral regions of the nervous system were also observed. Two stages of embryonic development were examined: Hamburger and Hamilton's²⁵ stage 13 (48-52 h of incubation), before significant neuronal birth, and stage 18 (3 days of incubation), when many neurones are withdrawing from the cell cycle ^{26,27}. Both stage 13 and 18 embryos were treated with demecolcine for 4 h before they were killed, as described elsewhere21

Before neuronal birth, the cells of the neural tube form a pseudostratified columnar epithelium—the neuroepithelium. They are a population of replicating cells that contain the precursors to neurones, glial cells and ependymal cells. During mitosis the cells lose their basal attachment to the external limiting membrane, assume a round shape adjacent to the neurocoel and undergo cytokinesis (see ref. 28). Treatment of the embyro with demecolcine arrests mitotic cells in metaphase and causes the IFs to aggregate and form a cable, or ring, around the cell's condensed chromatin. The IF in interphase cells also aggregate into cables in the presence of demecolcine, but these cells do not lose their bipolar shape and the IF cables are predominantly located in the basal processes. In this manner, treatment with demecolcine facilitates detection of small

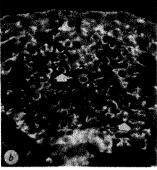

Fig. 1 Two exposures of a single microscopic field in a transverse section through the neural tube of a demecolcine-treated stage 13 embryo after staining with a, the fluorescent chromosome stain Bisbenzamid-H (Hoechst, H3325), and b, antiserum to FIF protein, localized by indirect immunofluorescence with a rhodamine-conjugated secondary antibody. Tissue preparation and immunofluorescence were performed as previously described²¹. Appropriate microscope filters allow separate visualization of the bisbenzimide and rhodamine. The metaphase cells appear as brightly staining areas of condensed chromatin (arrows in a). Associated with each of the metaphase cells is a ring labelled with anti-FIF (corresponding arrows in b). ×140.

amounts of IF proteins by immunofluorescence, and also allows the unambiguous association of IF aggregates with a specific metaphase cell. As we reported previously²¹, virtually all the metaphase cells in the stage 13 neural tube have FIF cables (Fig. 1), as determined by a fluorescent chromosome stain combined with immunofluorescent labelling using antiserum to FIF protein. None of these cables bind antibodies against the 70,000- or 180,000-NIF proteins, or the IF proteins characteristic of astrocytes or muscle cells.

In the stage 18 neural tube, as in stage 13, almost all (\sim 98%) the metaphase cells contain FIF cables. Unlike stage 13, however, some cells contain cables that bind antibodies to the 70,000- and 180,000-MW NIF proteins. Interphase nuclei positioned in the developing mantle layer have NIF-positive processes, presumably representing axonal formation and NIF synthesis in postmitotic neuroblasts. In addition, we were surprised to find that a small percentage (\sim 0.75%) of the metaphase cells surrounding the neurocoel also have NIF-positive rings (Fig. 2) and must therefore represent cells that have initiated synthesis of NIF before terminal mitosis. Furthermore, outside the neural tube, a population of cells in the vicinity of the otic vesicle is remarkable in that it has a high percentage of metaphase cells with NIF-positive rings (Fig. 3).

Double labelling of sections using antibodies against FIF and NIF shows that metaphase cells with NIF cables also contain FIF, although not always in the same distribution (Fig. 4a, b). Similarly, NIF-positive cables associated with interphase nuclei in the ventricular zone also have FIF (Fig. 4c, d). While some neuronal processes in the marginal layer of the stage 18 neural tube stain with both anti-NIF and anti-FIF, others bind only anti-NIF. At later stages all neuronal processes have no FIF and contain only NIF²¹.

These findings indicate a definite pattern of IF protein expression during neurogenesis in the spinal cord: (1) replicating neuroepithelial cells contain only FIF protein until the terminal cell cycle; (2) immediately before the final division the neuronal precursor cell begins to synthesize NIF proteins; (3) the postmitotic neuroblast expresses both NIF and FIF for a short period; and (4) with neuronal maturation, FIF expression ceases and only NIF proteins are detectable ^{10,21}.

The absence of NIF at embryonic stages before neuronal birth and the *de novo* appearance of NIF in replicating cells at a stage when neurones are withdrawing from the cell cycle indicates that the neuronal precursor cell initiates NIF synthesis during its terminal cell cycle. In this regard, molecular expression of neuronal differentiation occurs at least by the final S/G2 period of the precursor cell. This is consistent with the appearance of

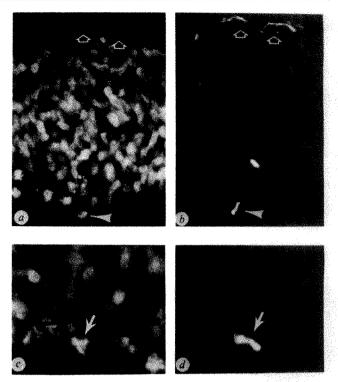

Fig. 2 Each pair of photographs shows one microscopic field of a section from a demecolcine-treated stage 18 neural tube stained with bisbenzimide (a, c) and antibodies to the 70,000-MW NIF protein (b, d). a, b, Interphase nuclei in the developing mantle1 layer (arrows) have associated NIF-containing processes. A metaphase cell (arrowhead) adjacent to the neurocoel has an NIF-positive ring lying perpendicular to the plane of section. NIF proteins are also associated with an interphase cell further from the neurocoel. $\times 280$. c, d, Arrow indicates a metaphase cell adjacent to the neurocoel with an associated NIF-positive ring. Note that many metaphase cells do not have NIF-positive rings. $\times 840$.

argentophilic filaments in replicating cells of the embryonic chick retina²⁹. In the central nervous system, in contrast to NIF proteins, other 'markers' of neuronal differentiation appear only in postmitotic neurones. G_{M1} ganglioside³⁰, neurone-specific enolase³¹ and adrenergic characteristics³² are not found in replicating neuronal precursors. However, replicating precursor cells of sympathetic neurones exhibit several characteristics of adrenergic neurones (that is, formaldehyde-induced fluorescence, dense-core vesicles and noradrenaline uptake)^{32,33}, suggesting that neuronal precursors derived from neural crest might express neuronal properties for one or more generations before the terminal cell cycle. In this regard, the high percentage of replicating cells with NIF cables in the vicinity of the otic vesicle may indicate that some neuronal precursor populations

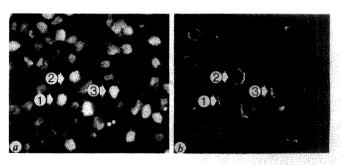

Fig. 3 A transverse section through a region postero-lateral to the otic vesicle from a demecolcine-treated stage 18 embryo stained with (a) bisbenzimide and (b) antibodies to the 70,000-MW NIF protein. A high percentage of metaphase cells in this region have associated NIF-positive rings. The numbered mitotic cells in a correspond to the numbered rings in b. ×380.

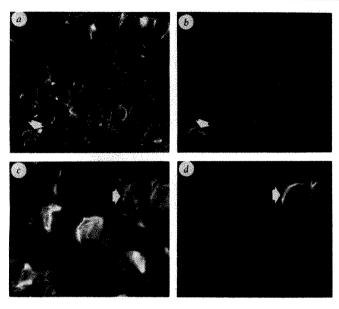

Fig. 4 Photographs of a demecolcine-treated stage 18 neural tube that has been double labelled with antibodies to FIF protein (a, c)and antibodies to either the 180,000-MW NIF protein (b) or the 70,000-MW NIF protein (d). a, b, Although most cells contain FIF, one (arrow) apparently has two cables, one mixed FIF and NIF cable and one pure FIF cable. × 560. c, d, Again, most cells contain FIF, but one cell migrating through the ventricular zone contains both NIF and FIF (arrow). ×840.

synthesize NIF for several generations. Alternatively, these cells may represent a neuronal population synchronously undergoing their terminal mitosis. Although the origin and fate of these cells remains to be determined, it is possible that they are derived from neural crest.

Finally, it is worth stressing that the early appearance of NIF reported here may represent a developmental sequence restricted to only certain types of neurones and may not apply to all neurones of the nervous system. Preliminary results indicate that for certain neuronal populations NIF expression follows, rather than precedes, the terminal mitosis. Further studies on NIF expression in different types of neurones are needed to understand the role of these proteins in development.

A second messenger required for nerve growth factor biological activity?

Rolf Heumann, Martin Schwab & Hans Thoenen

Abteilung Neurochemie, Max-Planck-Institut für Psychiatrie, D-8033 Martinsried, FRG

After binding to specific membrane receptors of target neurones and responsive phaeochromocytoma cells, nerve growth factor (NGF) is internalized and accumulated in the perikaryon within membrane-confined compartments (H. Rohrer et al., unpublished observation, and refs 1-5). Although quantitative electron microscopic autoradiography and ultrahistochemical studies gave no evidence for further movement of NGF^{1,2,4,5}, it was claimed on the basis of light microscopy of PC12 cells (ref. 6 and P.C. Marchisio, personal communication) that some of the NGF taken up by the cell reaches the free cytoplasm and subsequently the nucleus where it would exert a physiological effect. We report here that the direct introduction of NGF into the free cytoplasm of phaeochromocytoma cells by fusion with NGFloaded erythrocyte ghosts does not induce fibre outgrowth, in contrast to the normal response of these cells seen when NGF is added to the culture medium. Correspondingly, NGF antibodies introduced into the cytoplasm do not prevent fibre outgrowth evoked by NGF added to the culture medium. Thus, the binding of NGF to its receptor must result in the production of a second messenger either from the cell surface or after internalization from an intracellular compartment^{7.8}.

Guinea pig erythrocyte ghosts loaded with NGF or NGF antibodies (see Fig. 2 legend) served as vehicles for injecting these molecules into the cytoplasm of NGF target cells through cell fusion. The target cells were a line of PC12 phaeochromocytoma cells which reacted rapidly to NGF with an increase in choline acetyltransferase and induction of fibre outgrowth which occurred in 50-70% of single cells within 48 h. In addition to NGF or NGF antibodies, the ghosts were loaded simultaneously with two different marker proteins: fluorescein isothiocyanate-conjugated bovine serum albumin (FITC-BSA), serving as a marker to follow directly the fusion procedure by fluorescence microscopy; and horseradish peroxidase (HRP), to quantify the number of injected cells in fixed preparations. The loading efficiency of the ghosts, that is, the equilibration between the concentration in the loading solution (for details, see Fig. 2 legend) and the interior of the ghosts, depends on the molecular weight (MW) of the protein to be loaded. Accordingly, the 'loading efficiency' for ¹²⁵I-labelled NGF (MW 26,000) was 100%, whereas that for purified anti-NGF IgG antibodies (MW 150,000) was only 30%. The biological activity of NGF or NGF antibodies in the ghosts was tested by their ability either to induce fibre outgrowth or antagonize NGF-induced fibre outgrowth, respectively in PC12 cells. On the average, one loaded ghost contained about 44,000 molecules of NGF or a quantity of NGF antibodies able to neutralize about 26,000 molecules of NGF. Fusion of ghosts with target cells was performed in sparsely seeded monolayer cultures of the latter. In principle, we followed the fusion procedure of Schlegel et al. 10 with the modifications specified in Fig. 2 legend. The low temperature (4 °C) used reduced general cell damage during the 5-min exposure to polyethylene glycol (PEG). After fusion, the cells were kept in regular tissue culture conditions at 37 °C. Ghosts which had not fused detached from the cells during the next 6-12 h.

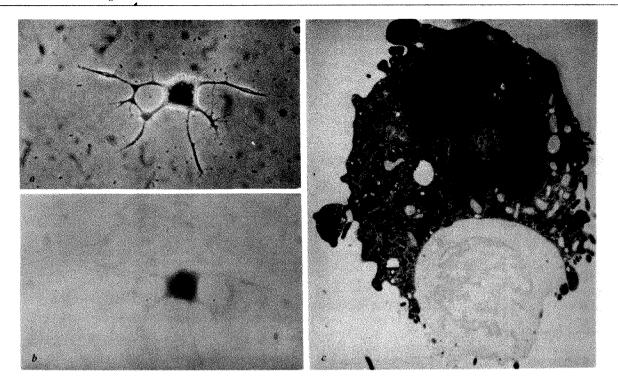

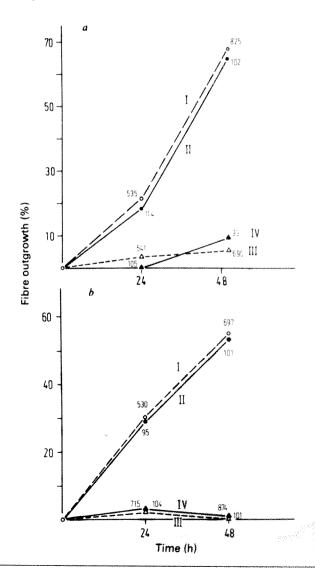

Fig. 1 Phase contrast (a), bright field (b) (same cell) and electron microscopic (c) photographs of fast-responding PC12 cells injected with HRP, FITC-BSA and NGF. The injection procedure is described in detail in Fig. 2 legend. The cells were grown in the presence of 50 ng ml⁻¹ NGF. The HRP reaction product¹⁸ is evenly distributed over the whole cell cytoplasm as well as the nucleus. The equal distribution of HRP in the free cytoplasm and the nuclear chromatin becomes impressively apparent in c which depicts neighbouring injected (top) and non-injected (bottom) cells. a, b, ×220; c, ×5,055.

Fig. 2 Effect of the injection of mouse NGF (a) or NGF antibodies (b) into PC12 cells. The loading procedure of the ghosts was essentially that of Yamaizumi et al.9. a, Guinea pig erythrocytes were equilibrated in 0.5 ml of 'reverse phosphate-buffered saline (PBS)' ('loading solution') containing 10 µg NGF, 0.3 mg HRP and 10 mg FITC-BSA (FITC/BSA = 2.4 in terms of molecules). The resulting ghosts were washed four times in Ca/Mg-free PBS (PBS-CMF: 8 g l $^{-1}$ NaCl, 0.4 g l $^{-1}$ KCl, 300 mg l $^{-1}$ KH $_2$ PO $_4$, 45 mg l $^{-1}$ Na $_2$ HPO $_4$ +7H $_2$ O, 1 g l $^{-1}$ glucose, 20 g l $^{-1}$ sucrose) and were finally resuspended at 10% (v/v) in the same buffer. The number of NGF molecules per ghost was determined by adding tracer quantities of ¹²⁵I-NGF (prepared by the lactoperoxidase method 19) to the loading solution. For electron-microscopic autoradiography 296 μ Ci of 125 I-NGF (178 \times 10 3 c.p.m. per ng) was used. The calculation of the loading efficiency was based on an average volume of $90~\mu m^3$ for guinea pig erythrocytes²⁰. Four days before the fusion experiments 30,000 'fast-reacting PC12' cells were plated on 35-mm polyornithine-coated dishes and cells were then incubated in Dulbecco's minimal essential medium (DMEM) containing 10% heat-inactivated horse serum and 5% heat-inactivated fetal calf serum. Cells were washed first with PBS-CMF, then with PBS-CMF containing 130 µg ml⁻¹ phytohaemagglutinin type V(Sigma), and finally $50 \mu l$ of ghost suspension (2%, v/v) corresponding to 1.2×10^7 ghosts were added to the cultures. After 4–5 min at $37 \, ^{\circ}$ C another $25 \mu l$ (0.6×10^7 ghosts) of the suspension were added and the cultures kept for 3–5 min at $37 \, ^{\circ}$ C. Plates were then washed carefully with 1 ml PBS-CMF and placed in a refrigerator (4 °C) for 2-3 min. Thereafter, 100 µl of ice-cold PEG 4000 (Roth, 45% (w/v) in PBS-CMF was added and cells were left at 4°C for 5 min. PEG treatment was terminated by addition of 1 ml DMEM (containing Ca2+, Mg2+). After 15-45 min at 37 °C the medium was changed to normal medium with serum. After 8-12 h (taken as time 0) the medium was changed and cells incubated in the presence of either 50 ng ml⁻¹ of NGF (curves I, II) or NGF antibodies (curves III, IV). The amount of NGF antibodies used was sufficient to neutralize all the NGF added previously to the cultures in loaded ghosts. At the times indicated cultures were fixed (2.5% glutaraldehyde, 20 min) and stained for HRP (30 min 0.03% diaminobenzidine, 2 h 0.03% diaminobenzidine plus 0.01% $\,\mathrm{H_2O_2})^{18}$. Randomly chosen regions of the plate were scored for fibre outgrowth (positive score for fibres ≥20 µm). The percentage of all the single cells carrying fibres was counted under phase contrast (curves I, III). Subsequently, the injected HRP-positive cells were evaluated under bright-field optics (curves II, IV). The number of cells counted per point are indicated and the injection frequencies can be directly derived from them. b, The same methods as described for a were used with the following modifications. Erythrocytes were loaded in 720 µl of a solution containing 504 μg affinity-purified NGF antibodies²¹ (neutralizing 40 μg NGF), 0.4 mg HRP and 10 mg FITC-BSA. At time 0 those plates which were subsequently incubated with 50 ng ml⁻¹ of NGF (curves I, II) were washed with NGFcontaining medium. Residual NGF antibody activity could be neutralized by this procedure. The rest of the plates received normal medium (curves III, IV). Injected cells (curves II, IV) and total cells (curves I, III) were evaluated as described for a.

The quantity of 125I-NGF present in the injected cells revealed that an average of six ghosts had fused with each cell. This high multiplicity is probably because the ghosts tended to aggregate with each other and so fusion took place between one PC12 cell and an aggregate of fused ghosts. The radioactivity in ¹²⁵I-NGF-injected cells decreased gradually over 2 days to ~30% of the initial value. About 50% of the radioactivity remaining after 2 days represented native NGF, as judged from its migration in SDS-polyacrylamide gel electrophoresis using a 15% gel. Thus, the quantity of native NGF present in a single injected cell amounts to an average of ~44,000 molecules 2 days after the injection. In comparison, when PC12 cells are incubated for 24 h with 100 ng ml⁻¹ of ¹²⁵I-NGF, the quantity of radioactivity accumulated (not corrected for possible degradation products) corresponds to ~15,000 molecules per cell—onethird of the amount of NGF injected. As shown in Fig. 1, the injected HRP is evenly distributed throughout the cytoplasm and nucleus of the cell. Electron microscopic autoradiography performed on the same sections indicated that the 125 I-labelled NGF, too, was distributed throughout the cell cytoplasm and also reached the nucleus.

The fusion procedure did not influence the NGF-mediated fibre outgrowth, that is, the frequency and extent of fibre outgrowth from injected cells in response to NGF added to the medium is the same as that of non-injected cells (Fig. 2). In those experiments where the response of the NGF-injected cells (in the absence of NGF in the culture medium) was studied, we supplied the medium with NGF antibodies to ensure that any NGF originating from leaking ghosts would not reach cellsurface NGF receptors. As demonstrated in Fig. 2a, the NGFinjected and non-injected cells behaved identically: fibre outgrowth occurred only if NGF was added to the culture medium. Conversely, if NGF antibodies were injected into the cytoplasm these antibodies did not interfere with fibre outgrowth produced by NGF in the culture medium (Fig. 2b). Preliminary results indicate that injected NGF is also unable to support the survival of neurones dissociated from 8-day old embryonic chick dorsal root ganglia or PC12 cells in serum-free medium (in serum-free medium PC12 cells need NGF for survival¹¹), whereas injected anti-NGF antibodies do not antagonize the ability of NGF in the culture medium to support the survival of these cells.

We conclude that even if an undetectably small proportion of NGF leaves the membrane-bound compartments in which it is always localized after receptor-mediated internalization, it would be unable to initiate the characteristic cellular responses to NGF-fibre outgrowth and cell survival. Thus the enhancement of polymerization of microtubules and microfilaments, demonstrated in the test tube in response to high concentrations of NGF¹²⁻¹⁴, must have no physiological significance in the context of fibre outgrowth, and the binding of NGF to chromatin isolated from chick dorsal root ganglia¹⁵ cannot be responsible for fibre outgrowth or for survival. The biological effects of NGF must be mediated by an interaction with specific cell-surface receptors and the generation of (a) second messenger(s) rather than by a direct action of intact NGF in the free cytoplasm or the nucleus.

The nature of the second messenger and its site of production (cell surface or cell interior after internalization) are unknown. In adrenergic neurones NGF binds to receptors or nerve terminals and is subsequently transported within vesicles and cisternae to the cell body. There, fusion of the transport vesicles with other intracellular membrane systems and eventually with lysosomes can be observed^{2,5}. It cannot be excluded that a cleavage product of NGF is transferred into the cytoplasm as is the case for diphtheria toxin where a fragment of the original toxin molecule is transferred across the membrane into the free cytoplasm where it exerts its blocking action on ribosomal protein synthesis 16,17. It is also possible that the NGF-receptor complex is transferred into the cytoplasm, although no such mechanism involving a polypeptide hormone and its receptor has previously been described. If NGF should be cleaved or bound to its receptor before transfer into the cytoplasm, then our results show that the resulting secondary product(s) of NGF or NGF-receptor complexes are not recognized by the antibodies raised against native NGF.

We thank Mrs M. Reitmayer and Ms Ch. Müller for technical assistance, Drs D. Edgar and Y.-A. Barde for their critical review, and Mrs U. Grenzemann for typing the manuscript.

Reversal of transplantation immunity by liver grafting

Naoshi Kamada, H.ff.S. Davies & Bruce Roser

Department of Immunology, ARC Institute of Animal Physiology, Babraham, Cambridge CB2 4AT, UK

The transplantation of organs between individuals of a species normally has two main consequences: (1) the tissue is rejected unless the individuals are matched for identity of transplantation antigens, especially those encoded by the major histocompatibility complex (MHC), and (2) the recipient is sensitized to the transplantation antigens of the donor so that second-set grafts are rejected in a more violent manner1. These rules of transplantation are not obeyed by liver grafts. Orthotopic transplants of liver are never rejected by many strains of rat even though the MHC barrier is crossed². We have recently shown that instead of sensitizing the recipient, these enduring liver grafts induce a state of donor-specific unresponsiveness in which subsequent grafts of other organs, such as skin, are accepted permanently. It is possible that many strains simply cannot mount a sufficiently vigorous destructive immune response to outstrip the liver's great capacity to repair immune damage and that the systemic unresponsiveness observed is due to diversion of alloreactive lymphocytes with donor specificity into the liver allograft. Manipulations which increase the vigour of the immune response might therefore tip the balance in favour of liver graft rejection and away from induction of unresponsiveness. We have previously measured the degree to which the immune response can be increased by previous exposure to MHC antigens in a quantitative adoptive transfer system3. In the strain combination DA (MHC haplotype RT-1*) grafted to PVG (RT-1°), the lymphocytes of immunized animals are 1,000 times more potent than those of non-immune animals in procuring graft destruction when transferred to irradiated hosts. Unexpectedly, we have now found that liver grafts transplanted into previously immunized rats not only fail to reject but convert the state of heightened reactivity to donor grafts characteristic of immune recipients into one of non-reactivity characteristic of tolerant animals.

Table 1 Induction of tolerance to MHC antigens by liver transplantation is systemic

Days after DA	Days of skin graft survival (no. of rats)						
liver grafts	DA	AO					
0	10, 12, 13, 14(2), 18	8, 9, 12					
5	13, 14, 15, 22, 100 (2)	11, 12 (2)					
15	23* > 100(5)	13 (2), 14					
45	65*, 88*, >100 (4)	13 (2), 15					

PVG rats received an orthotopic transplant of liver from DA donors on day 0 and then an orthotopic skin graft from both DA and AO (third party) donors on the day indicated. By day 15 some recipients were systemically tolerant of the DA alloantigens, as indicated by permanent survival of the indicator DA skin graft in perfect cosmetic condition. By day 45 all animals were tolerant. The specificity of this tolerance was absolute, as indicated by rejection of all third party (AO, RT1^u) skin grafts.

* These animals died with a perfect DA skin graft in place.

The technique for orthotopic liver transplantation used in these experiments is reported in detail elsewhere⁴. Surgical technique is not a significant variable in this series, as indicated by a 95% permanent survival rate of the past 72 DA to PVG liver transplants performed here (Fig. 1). Although DA livers transplanted to PVG recipients are never rejected, skin grafts are rejected in 8 days, heart grafts in 7-8 days and kidney grafts in 9-10 days. The reason for the prolonged survival of the liver in the rat and in other species⁵ is still being studied in this and in other laboratories, but it is not due to a failure of the recipients to mount an immune response against liver tissue. Indeed, the degree of early mononuclear cell infiltration, blast transformation and liver cell necrosis, as assessed histologically, is almost as great in PVG recipients which do not reject as in BN recipients which do (N.K., Wight and B.R., in preparation). The response in PVG rats is ephemeral, only minimal histological changes being detectable several months after grafting, whereas the response in BN rats is progressive.

While grafting with skin, heart or kidney provokes vigorous immunity, grafting with liver rapidly induces a state of systemic unresponsiveness (Table 1). Thus, within 15 days of liver transplantation, recipient rats become specifically unresponsive to subsequent skin grafts from the DA strain while retaining the capacity to reject third party (AO, RT1") strain grafts. This state of unresponsiveness is associated with the presence of specific blocking material in the circulation and deletion of the clones of cells required for DA graft rejection from the peripheral lymphocyte pool, but there is no evidence of cell-mediated suppression (data not shown).

Because we had previously established that immunization to antigens of the MHC in this strain combination led to a large

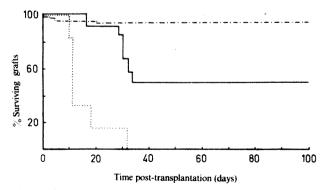

Fig. 1 Survival of liver grafted rats. Apart from three early technical failures⁵, 69 normal PVG rats grafted with DA livers (---) survived indefinitely while BN rats grafted with DA livers (...) all died within 32 days. When PVG rats were sensitized by rejection of DA skin grafts 28 days before liver transplantation (---), 50% behaved as high responder animals, rejecting their liver grafts within 34 days, while 50% failed to reject and survived indefinitely.

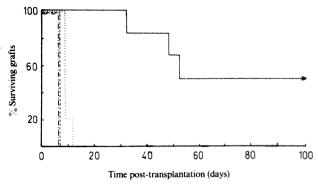

Fig. 2 Immune status of liver grafted rats. PVG rats, immunized to DA antigens, which had survived subsequent grafting with DA livers, were challenged with another DA skin graft 28 days after liver transplantation (——). All rats showed very prolonged survival of the second-set DA skin graft and 50% of animals retained the skin graft indefinitely. Where no liver graft intervened between the two DA skin grafts (-···) or where the liver graft was syngeneic with the recipient PVG (----), the second skin graft was rapidly rejected in second-set tempo. Substitution of third party (AO) antigens at the immunizing and challenge stages (····) showed that the DA liver graft was not nonspecifically immunosuppressive: the second AO skin grafts, placed after DA liver transplantation on PVG rats immunized by prior skin grafts, were all promptly rejected.

increase in the efficiency of heart graft rejection as measured in a quantitative adoptive transfer assay3, we felt confident that immunization would convert the non-rejector PVG to a rejector strain of equivalent potency to BN. Surprisingly, 50% of 12 previously immunized animals survived indefinitely after subsequent DA liver transplantation (Fig. 1). In those six animals which died after liver grafting, histological examination revealed a severe destructive immune response characterized by heavy mononuclear cell infiltrates and widespread hepatocellular necrosis. In the six animals which survived long-term, the livers showed minimal signs of tissue destruction and no significant cellular infiltrate (a picture similar to that seen longterm in normal rats in receipt of DA liver grafts). It was therefore of interest to determine whether, like normal nonimmune graft recipients, the immune animals had also become systemically tolerant to DA MHC antigens during the recovery phase. This proved to be the case. Subsequent skin grafts applied to such animals failed to reject in 50% of cases, for over 100 days (Fig. 2). The antigen specificity of this phenomenon was shown in two ways. One group of immunized animals received a syngeneic (PVG) liver graft instead of a DA graft. This has no suppressive effect on the second-set rejection of DA skin (Fig. 2). Another group of PVG rats was immunized against third party AO (RT1^u) antigens instead of DA (RT1^a) antigens before receiving a DA liver graft. In this group the fully allogeneic DA liver graft did not induce cross-tolerance to AO antigens, as indicated by rejection of all subsequent AO indicator skin grafts.

Using easily enhanced rat strains, Bowen et al. demonstrated a slight weakening of immunity against F, hybrid kidney grafts by temporary parabiosis of hyperimmune animals to animals bearing enhanced kidney grafts. Kawamura et al.8, again using F₁ hybrid kidney grafts, demonstrated that second-set grafts of identical type often have prolonged survival especially if the recipient animal was unable to reject the first graft promptly. However, they could only demonstrate this phenomenon where exposure to the first graft had not led to detectable sensitization of the recipient9. We believe this to be the first observation of specific conversion of a state of transplantation immunity against a full haplotype MHC difference to a state of tolerance. It had previously proved impossible both clinically and experimentally to erase memory of previous exposure to antigens of the MHC even with such potent immunosuppressive agents as cyclosporin A¹⁰. The facility with which liver transplantation achieves this result in a high proportion of animals undermines

the simple quantitative explanation of liver graft survival outlined in the introduction and obviously deserves further study. Of particular interest will be the analysis of the efficacy of liver tissue in the form of an intact organ or as dispersed cells in modifying the alloreactive repertoire of normal and immune animals.

Immune (γ) interferon produced by a human T-lymphoblast cell line

Ilana Nathan, Jerome E. Groopman, Shirley G. Quan, Noelle Bersch & David W. Golde*

Division of Hematology-Oncology, Department of Medicine, UCLA School of Medicine, Los Angeles, California 90024, USA

(IFNs) are glycoproteins with antiviral. Interferons immunomodulatory and antiproliferative properties. They are classified on the basis of their acid stability, antigenic properties, stimuli for production and cellular origin. IFN- α and IFN- β are acid-stable and derived from leukocytes and fibroblasts. IFN-y (immune, type II) is acid-labile and generally derived from T lymphocytes. Elaboration of IFN-y occurs either after sensitized T lymphocytes are exposed to specific antigen or on induction of T lymphocytes with mitogens^{1,2}. IFN- α and IFN- β have been extensively characterized and much is known about their biochemical properties and gene structure³⁻¹¹. In contrast, there is relatively little information available regarding the physical and biological properties of human IFN-y (refs 1, 2, 12-17). Particular interest in IFN-y derives from in vitro and in vivo studies which indicate that IFN-y has greater antiproliferative effects on neoplastic cells than IFN- α and IFN- β (refs 18-21). We report here the production and characteristics of IFN-γ elaborated by a unique human T-lymphoblast cell line.

The paucity of data regarding IFN-y is largely related to difficulties in obtaining large quantities of purified material. In our laboratory, a human T-lymphocyte cell line (Mo) has been derived from the spleen of a patient with a T-cell variant of hairy-cell leukaemia that produces IFN-y and other lymphokines. The Mo cell line has been described in detail elsewhere 22-26.

The Mo cells constitutively produce low levels of interferon, both in the presence and absence of serum, and its production is not enhanced by exposing the cells to Sendai virus or polyinosinic polycytidylic acid. We tried to induce IFN-γ production using T-cell mitogens as well as chemical agents (Table 1). Induction with phytohaemagglutinin (PHA) markedly increased the production of IFN-y. As the ranges in Table 1 demonstrate, there was considerable variability in the titres elaborated in each induction regimen. Interferon production by Mo cells in culture was maximal after 3 to 4 days of incubation with PHA, thus the conditioned media used in all experiments were collected after 4 days of induction.

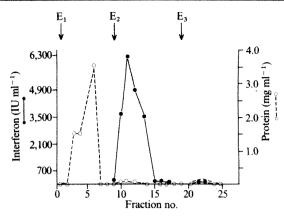

Fig. 1 Chromatography of Mo IFN-y on Con A-Sepharose. Conditioned medium containing 2% FCS induced with 3% PHA. 1 μM dexamethasone and 0.5 mM sodium butyrate was dialysed for 16 h at 4 °C against 100 volumes of PBS, pH 7.4 (E₁). The Con A-Sepharose (Pharmacia) column (0.9×5 cm) was equilibrated with PBS, and 5 ml of dialysed conditioned medium applied. The column was washed with PBS then developed with 0.2 Mα-Dmethyl mannoside in PBS (E₂) at a flow rate of 2 ml h⁻¹. The column was developed with 0.2 M \alpha-D-methyl mannoside and 20% ethylene glycol in PBS (E₃). Protein was determined using a dye binding procedure (Bio-Rad). Solid line represents interferon activity and broken line, protein concentration.

It has been shown 15,17,27,28 that chemical agents known to affect cell differentiation in vitro may enhance IFN production. The phorbol ester, 12-O-tetradecanoylphorbol-13-acetate (TPA) proved to be a potent enhancing agent of IFN-y production by the Mo cells. Levels of up to 43,400 international units (IU) per ml per 10^6 cells were achieved in the presence of 2%fetal calf serum (FCS), 3% PHA and TPA (10 ng ml⁻¹). However in serum free conditions, PHA induction alone gave maximal interferon yield with specific activities of $\sim 2 \times 10^4$ IU per mg protein. Concanavalin A (Con A; 20-40 µg ml⁻¹) also induced IFN-y production but its effect was substantially less than that observed for PHA (data not shown).

Mo interferon proved to be entirely of the γ type by the criteria of acid lability, stimulus of induction, kinetics of production and failure of neutralization by antisera to leukocyte interferon (data not shown). The antiviral activity in Mo-conditioned medium was totally inactivated on reduction to pH 2 with 0.1 M HCl or 0.5 M citrate buffer. Also, Mo IFN-y is heatlabile, losing >98% activity when incubated at 56 °C for 1 h or on boiling for 1 min (Table 2). This observation is consistent with previous reports which indicate that mitogen-induced IFN-y is heat-labile 12,14. We examined the effect of various denaturing agents on the IFN-y and found that it was almost completely inactivated with 8 M urea, 6 M guanidine hydrochloride, 0.1% SDS and 0.01% zwitterionic detergent. However, note that there was retention of activity after incubation with 10 mM β-mercaptoethanol (Table 2), suggesting that, while disulphide linkages may be present in the molecule, they are not critical for antiviral activity. The activity of Mo IFN-y is completely destroyed by pronase (Table 2).

The chromatographic behaviour of Mo IFN-y on Con A-Sepharose is shown in Fig. 1. The bulk of the protein applied to the column passed through unretarded and this material contained only negligible amounts of interferon activity. The bound interferon was recovered by elution with 0.2 M α-Dmethyl mannoside in phosphate-buffered saline (PBS; pH 7.4) giving a purification of ~ 20 -fold to a specific activity of $6-8 \times$ 10⁴ IU per mg protein; 96% of the interferon activity loaded was recovered in the α -D-methyl mannoside eluate. Only 0.5% of the applied activity was recovered after elution with 20% ethylene glycol, 0.2 M α -D-methyl mannoside in PBS. These results suggest that almost all the Mo IFN- γ is glycosylated. It has previously been reported²⁹ that human IFN-y induced in

^{*} To whom reprint requests should be addressed

Table 1 Induction of IFN-y from Mo cells

	IFN titre (IV per ml per 10 ⁶ cells)		
	Mean	Range	
Serum-free medium			
Uninduced	35	5-50	
PHA	1,900	200-3,200	
$PHA + TPA (10 \text{ ng ml}^{-1})$	1,100	800-1,200	
Medium + serum (2% FCS)			
Uninduced	66	50-75	
PHA	5,700	900-9,400	
PHA + dexamethasone $(1 \mu M)$	4,350	2,700-6,000	
PHA + butyrate (0.5 mM)	4,100	900-7,900	
PHA + butyrate (0.5 mM) +			
dexamethasone (1 µM)	5,150	3,500-7,900	
$PHA + TPA (10 \text{ ng ml}^{-1})$	16,900	7,871–43,400	

The Mo cells were cultured in α medium (Flow) containing 20% FCS (screened lot). Interferon production, unless otherwise stated, was achieved by washing the cells three times with α medium and then culturing 10^6 cells ml⁻¹ for 4 days in α medium alone (serum-free) or in α medium containing 2% FCS. Inducers used were: phytohaemagglutinin (PHA; HA 15 reagent grade, Wellcome), sodium butyrate (Pfaltz & Bauer), dexamethasone (Sigma) and TPA (PL Biochemicals); these were added to the culture at the concentrations shown. PHA was present at 2% and 3% in serum-free and serum-containing cultures, respectively. The antiviral activity of interferon was determined by quantitation of the cytopathic effect of murine encephalomy-ocarditis virus on the foreskin fibroblast cell line CCL54 trisomic for chromosome 21 (ref. 30). All interferon units are expressed with reference to the NIH human leukocyte interferon standard (G-023-901-527). Titres are the results of four separate experiments.

leukocytes by PHA shows chromatographic heterogeneity on Con A-Sepharose, presumably resulting from varying degrees of glycosylation. In contrast, the Mo IFN-γ appears more homogeneous with respect to its glycosylation.

The hydrophobic nature of human IFN- γ has been described in previous studies¹²⁻¹⁴. Crude Mo-conditioned medium, induced in the presence of 2% FCS with 3% PHA, 0.5 mM butyrate and 1 μ M dexamethasone, was applied to a controlled-pore glass (CPG) 350-B mesh size 120/200 column (Electronucleonics). All the interferon activity was absorbed onto the column while 98% of the protein was voided. Elution with 1 M NaCl, 20% ethylene glycol in 0.2 M phosphate buffer (pH 7.4) recovered 2% of the loaded protein and almost all the interferon activity, giving a \sim 50-fold purification and a specific activity of \sim 10⁵ IU per mg protein.

Reported molecular weights (MWs) for IFN-γ have ranged from 20,000 to 80,000— these discrepancies may be related to molecular heterogeneity and binding to other proteins. Gel-

Table 2 Characterization of Mo IFN-y

Treatment	Residual interferon activity (% of control)
Urea (8 M)	4
Guanidine HCl (6 M)	0.7
β-Mercaptoethanol (10 mM)	100
SDS (0.1%)	0
Zwitterionic detergent (0.01%)	9
56 °C (1 h)	1.6
100 °C (1 min)	1.8
Pronase (0.1 mg ml ⁻¹)	< 0.1
pH 2	0

Conditioned medium containing 2% FCS obtained from Mo cells cultured with 3% PHA and 10 ng ml $^{-1}$ TPA was used. All treatments except heat and pronase inactivation were performed at 37 °C for 1 h. The material was then dialysed against 100 volumes of PBS, with two exchanges. Pronase (Sigma) was incubated with serum-free conditioned medium from cells induced with 2% PHA alone at 37 °C for 1 h. Control incubations with 2% FCS contained 2,000 IU ml $^{-1}$ interferon activity whereas the serum-free material had 3,200 IU ml $^{-1}$.

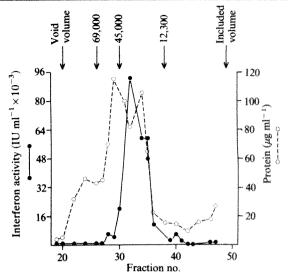

Fig. 2 Gel filtration of Mo IFN-γ. Serum-containing conditioned medium from Mo cells induced with 3% PHA and TPA (10 ng ml⁻¹) was partially purified on CPG beads and then applied to an Ultrogel AcA 44 (LKB) column (0.9×40 cm) equilibrated with 20% ethylene glycol, 1 M NaCl in 0.02 M phosphate buffer, pH 7.4. Column was developed with the same buffer at a flow rate of 2.2 ml h⁻¹. Fractions of 0.75 ml were collected. Molecular weight standards were: blue dextran (void volume), bovine serum albumin (MW 69,000), ovalbumin (MW 45,000), cytochrome c (MW 12,300) and 4-methylumbelliferone (included volume). Solid line represents interferon activity, and broken line, protein concentration.

filtration chromatography of serum-containing conditioned medium was performed using an Ultrogel AcA 44 column. An initial peak of interferon was obtained with the PBS elution at \sim 70,000 MW. The specific activity of this material was ~10⁴ IU per mg protein. Two smaller peaks of interferon activity were obtained with 1 M NaCl elution and then with 1 M NaCl, 20% ethylene glycol. The secondary peaks may represent species of interferon exhibiting ionic or hydrophobic interaction with the Ultrogel beads. To examine further the size characteristics of the Mo IFN-y, we applied material partially purified on CPG beads to a similar Ultrogel AcA 44 column (Fig. 2). To avoid ionic or hydrophobic interactions and focus solely on its gel-filtration properties, the column was developed using 1 M NaCl, 20% ethylene glycol in 0.02 M phosphate buffer (pH 7.4). A single peak of activity was obtained with an apparent molecular weight of ~40,000 and a specific activity of 1.2×10^6 IU per mg protein. It is possible that the high-molecular weight species observed when crude conditioned medium was applied directly to the gel-filtration column represented binding of Mo IFN-y to carrier proteins present in serum.

Mo IFN- γ is a hydrophobic glycoprotein which is elaborated in high titre on induction with T-cell mitogens and various chemical agents. It is clear from its physicochemical characteristics that the Mo IFN- γ is distinct from the erythroid-potentiating activity, colony-stimulating activity and neutrophil migration-inhibitory factor also produced by this cell line $^{22-26}$. As the Mo cell line is a homogeneous population of T lymphoblasts, the results suggest that IFN- γ may be induced by lectins without the need for cooperation by other cell types².

The Mo cell line provides a unique source of human IFN- γ , and should allow the large-scale production of IFN- γ for purification and clinical trials. It may also be of use in isolating the human gene(s) for IFN- γ .

Establishment of a human T-cell hybrid line with suppressive activity

Catherine Grillot-Courvalin & Jean-Claude Brouet

Laboratory of Immunochemistry and Immunopathology, INSERM U 108, Research Institute of Blood Diseases and Laboratory of Oncology and Immunohematology of CNRS, Hôpital Saint-Louis, 75475 Paris Cedex 10, France

Roland Berger & Alain Bernheim

Laboratory of Cytogenetics, Hôpital Saint-Louis, 75475 Paris Cedex 10, France

The construction of murine B hybridomas producing homogeneous specific antibodies in almost unlimited quantities has led to major progress in immunology1. Recently, human B hybrid lines secreting antibody of defined specificities have also been established^{2,3}. Similarly, murine T hybrids have been obtained which may produce specific immunoregulatory factors such as antigen-specific suppressor factors 4-6, T-cell replacing factor7 or allogeneic effect factor8. The availability of functional T hybrids in man should allow a better understanding of human lymphocyte interaction and regulation. We describe here the fusion of a permanent human T-cell (KE37) with peripheral blood T lymphocytes to produce a human T hybridoma line which has a stable hypotetraploid karyotype and continuously produces a factor which suppresses pokeweed mitogen (PWM)induced B-cell differentiation.

The permanent T-cell line used for hybridization was KE37, which has been derived from a human acute lymphocytic leukaemia (provided by H. G. Kunkel and S. M. Fu). A 5bromodeoxyuridine (BUdR)-resistant variant of this line was selected after mutagenesis to obtain a line deficient in thymidine kinase and therefore sensitive to the hypoxanthine-aminopterine-thymidine (HAT) medium⁹. This variant line was then subcloned by limiting dilution. We fused one of these clones, D1R11, with peripheral blood lymphocytes (PBL) from a patient who presented with a variable agammaglobulinaemia and a moderate blood T-cell hyperlymphocytosis (5,000 mm⁻³); most of these T lymphocytes expressed Ia antigen and showed a

Table 1 Cell-surface phenotype of parental and hybrid cells (expressed as percentage of positive cells)

	Surface Ig	E rosettes	Т3	T4	Т5	Т6	Т8	T10	T11	Ia
DE	0	20	73	15	50	0	50	NT	NT	60
D1R11	0	10	0	0	0	100	10	50	4	0
$DE \times D1R11$	0	70	0	0	0	100	100	100	100	0

10×10⁶ cells from a subclone (D1R11) of the thymidine kinasedeficient variant of KE37 T-cell line were fused with 10×10^6 peripheral T cells from donor DE. For the fusion the parental cells were washed twice with Dulbecco's minimal essential medium (DMEM) without fetal calf serum (FCS), the last washing being performed in the presence of 5% dimethyl sulphoxide (DMSO). The pellet was then resuspended in 0.5 ml of 33% (w/v) polyethylene glycol (PEG) (molecular weight (MW) 4,000; Sigma), left for 3 h at 37 °C then centrifuged for 3 h at 200g. The supernatant was carefully discarded, the cells gently resuspended in DMEM plus 20% FCS then placed in 24-well Costar microlitre plates at a concentration of 1×10^6 cells per well, with a feeder of rat fibroblasts $(0.1 \times 10^6$ cells per well). Selective HAT medium (aminopterin, 4×10^{-7} M; thymidine, 1.6×10^{-5} M; hypoxanthine, $1.1 \times$ ⁴M) was added on days 2, 4, 8 and 10 after fusion, then replaced by HT medium for 6 days. Surface markers were studied on parental cells and on a given hybrid clone (DE×D1R11). Surface immunoglobulin (Ig) was detected with rhodamine-conjugated F(ab')₂ fragments of rabbit IgG antibody to human immunoglobulin. Monoclonal antibodies to Ia and T-cell antigens (designated T3, T4, T5, T6, T8 and T10) were detected by immunofluorescence using a second layer of fluoresceinconjugated IgG from a goat anti-mouse immunoglobulin serum (Nordic).

suppressor/cytotoxic antigenic phenotype (Table 1) as defined by the series of monoclonal OKT antibodies developed by Reinherz and Schlossman (reviewed in ref. 10; provided by G. Goldstein from Ortho Research Laboratory)

The fusion protocol used is described in Table 1 legend. In this, as well as in other experiments which used a variety of normal or stimulated T cells fused with either KE37 subclones or two other T-cell lines (JM and CEM), we found that the yield of hybrid clones was low; in this fusion 1 well out of 24 contained hybrids and their growth was delayed by 3-5 weeks. Subcloning the parental KE37 variant possibly improved the efficiency of fusion but it seems that human T-cell hybrids require special culture conditions during their initial growth phase. The hybrid nature of the clone (DE×D1R11), the functional properties of which are reported here, was documented by cytogenetic analysis and HLA phenotyping. The cells showed a stable hypotetraploid karyotype after 15 days to 6 months of continuous culture. Moreover, the presence of two morphologically distinct Y chromosomes, each from one parental cell, was shown using the quinacrine fluorescence technique (QFD) (Fig. 1). Although HLA typing of these hybrid cells was difficult because of their susceptibility to complement, they expressed definitely the HLA-A₂ antigen from DE, which was absent from the parental line, together with HLA antigens from KE37.

The hybrid line was studied for expression of several T-cell markers. The percentage of E rosette-forming cells was low in the D1R11 clone and varied from 25 to 75% in the hybrid line. However, when observed by immunofluorescence using a monoclonal antibody (OKT₁₁) to the E rosette-receptor, all DE×D1R11 cells were positive whereas <5% of cells of the parental cell line were stained. The staining by indirect immunofluorescence of DE×D1R11 cells using a rabbit antiserum to peripheral T cells¹¹ was much stronger than that of D1R11 cells. Additional studies were done using monoclonal antibodies to T cells (Table 2). Note that T6 (a common thymocyte antigen), which was absent on DE but present on D1R11 cells, was found on all hybrid cells. The T8 antigen, which was present on only a small fraction of D1R11 cells but found on most normal parental T cells, was expressed on all the hybrid cells. In contrast to T8, T5 antigen was absent from the hybrids although found together with T8 on DE lymphocytes (T5 and T8 define the suppressor/cytotoxic T-cell phenotype). T3 antigen was not detected on the hybrids although it is always associated with T5 and T8 on normal PBL as well as on the DE cells which were used in the fusion. Similarly, Ia antigens were not detectable by immunofluorescence on hybrids despite their expression on most DE T cells. Whether these findings reflect merely a lack of sensitivity of the assay, a chromosomal loss or possibly a complex regulation of T-cell antigen expression in hybrid cells is unknown.

Most interestingly, the hybrid line DE×D1R11 showed functional properties. As the normal cells used for fusion were obtained from a patient with agammaglobulinaemia and with a high number of circulating lymphocytes having the phenotype of activated suppressor/cytotoxic T cells (Ia, T5, T8 antigens) we determined whether the hybrids might produce a soluble factor with suppressive activity on polyclonal immunoglobulin production. As shown in Table 2, the supernatant of the hybrid line, and not that of D1R11, suppressed the generation of cytoplasmic immunoglobulin (cIg)-positive cells from normal PBL stimulated by PWM. The suppression ranged from 50 to 75% (mean 65.5%) at day 6 or 7. When tested with monospecific antisera to the various immunoglobulin chains, the isotypic distribution of cIg cells was not modified. The suppressive effect was observed when the supernatant was added at a final concentration of 10% and was maximum at a concentration of 20%. Note that this factor was produced without any triggering of the hybrid cells.

As the stimulation of murine T hybrids by lectins may enhance the production of soluble mediators, we also tested supernatants obtained in the presence of concanavalin A (10 µg ml⁻¹). In nine such experiments (data not shown) the suppression observed with DE×D1R11 supernatant compared with that of D1R11 supernatant ranged from 55 to 90% (mean 70%), which does not differ from the above results.

Experiments now in progress will attempt to characterize the biochemical nature of this factor as well as to determine its target cell. Until now, human suppressive factors have been shown to act either on T cells or at the B-cell level 12-14. No interferon was detectable in our supernatants and the hybrid cells did not carry Fc receptors for IgG, which are believed to modulate B-cell differentiation 15,16. Results of preliminary experiments indicate that the factor does not prevent PWM-induced mitogenesis; it has to be added in the first 36 h of culture to suppress PWMinduced B-cell differentiation, and it has no effect on B-cell

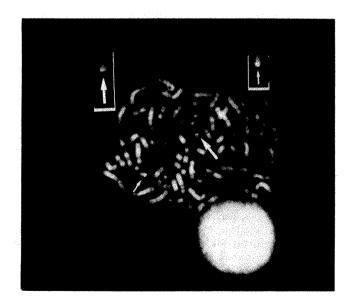

Fig. 1 Hypotetraploid (78 chromosomes) metaphase of DE× D1R11 hybrid clone. QFD staining shows two different Y chromosomes: one long chromosome from the T-cell line (main picture small arrow) and the second, small one originating from DE cells (main picture, large arrow). Inset right, DE×D1R11 long Y chromosome; inset left, DE × D1R11 small Y chromosome.

Table 2 Effects of supernatants from T-cell line (D1R11) or hybrid clone (DE × D1R11) on PWM-induced B-cell differentiation

PBL+PWM+DE×D1R11 supernatant	7.5	52	4	71	1.5	75	3.3	64

Peripheral blood mononuclear cells from four normal donors were cultured for 7 days in the presence of 50 µg ml⁻¹ PWM with or without added supernatants (final dilution 20%) from the T-cell line D1R11 or DE×D1R11 hybrids. These supernatants were collected after 18 h culture of 2 × 106 cells ml-1 in DMEM plus 10% FCS. a, Percentage of cells with cytoplasmic immunoglobulin (cIg) estimated for at least 1,000 cells on day 7 of culture, detected by immunofluorescence of fixed cells treated with fluorescein-conjugated goat IgG antibody to human immunoglobulin. The number of cells and viability were similar in each case. b. Per cent suppression of the expected number of clg cells per

differentiation induced by Nocardia, a relatively T-independent polyclonal activator of B lymphocytes.

We have shown here that construction of hybrids with activated human T cells of homogeneous phenotype is feasible; availability of such functional T hybrids will be valuable in the production and characterization of human T-cell factors and possibly also T-cell receptors.

We thank Professor M. Seligmann for help and advice during this study; Dr M. Fellous for preparing the BUdR-resistant variant of KE37, Mrs C. Dehay for HLA typing and Mrs A. Chevalier for technical assistance.

Switch region of immunoglobulin C_{μ} gene is composed of simple tandem repetitive sequences

Toshio Nikaido, Sumiko Nakai & Tasuku Honjo

Department of Genetics, Osaka University Medical School, Kita-ku, Osaka 530, Japan

Immunoglobulin heavy (H) chain genes comprise a family of variable region (V) genes and several constant region (C) genes which are classified, in mouse, into five major classes: μ , γ , α , δ and ϵ . During differentiation of a given B lymphocyte, a specific V_H gene is first expressed as a part of the μ-chain and at a later stage the expressed H chain switches the C region from μ to γ or α without alteration of the V_H region sequence 1-3. This phenomenon, called immunoglobulin class switch, involves a unique recombination event that takes place at the region 5' to each CH gene during B-lymphocyte differentiation 4-6. The

regions responsible for the class switch (or S-S) recombination are defined as switch (S) regions4. Recent structural analyses, which have revealed that S regions comprise tandem repetition of short unit sequences⁷⁻¹⁰, have allowed us to define the S region on a structural basis. The nucleotide sequences of S regions vary among different classes of CH gene, inevitably raising the possibility that the S_µ sequence contains separate subsets of sequences, each of which may pair with the S region of a different class. To test this possibility it is necessary to characterize the whole S, region. However, because the µ-gene clones isolated by other groups^{5,11,12} have lost a major portion (~3 kilobases [kb]) of the central core of the S_{μ} region, only a small part of the S_{μ} region sequence has been determined^{8,10,12,13}. We have now characterized the complete S_{μ} region by nucleotide sequence determination and restriction enzyme cleavage, and have found that it comprises simple tandem repetition of two kinds of 5-base pairs (bp) unit sequences, GAGCT and GGGGT. The nucleotide sequence of the S_{μ}^{-} region shares short common sequences with all the other S-region sequences. The results clearly exclude the abovementioned possibility and support the proposal^{7,9,10,13} that S-S recombination is mediated by repetitive homologous short sequences.

The 13-kb EcoRI fragment coding for the C region of the immunoglobulin μ -chain was previously cloned from newborn BALB/c mouse DNA using λ gtWES· λ B as vector (ref. 4). The recombinant phage and the insert were referred to as λ gtWES·IgH701 and IgH701, respectively. We have shown by Southern blot hybridization⁴ that IgH701 is indistinguishable from the germ-line C_{μ} -gene fragment. The 13-kb fragment was isolated by agarose gel electrophoresis and the fragments produced by HindIII digestion were subcloned into the HindIII

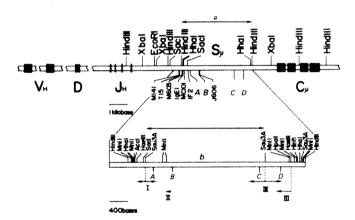

Fig. 1 Restriction endonuclease cleavage map of the S_u region and strategy for sequencing. The 3.7-kb HindIII fragment (Hind-A) which contained the S_{μ} region was subcloned in pBR322 and purified according to the method of Clewell and Helinski² Restriction cleavage sites were determined by combined cleavages of two or more enzymes. Restriction enzyme cleavage sites (EcoRI, HindIII, SacI, HhaI, XbaI and AccI) of IgH701 and the location of J_H segments were determined previously 4,12,14. Sources of restriction enzymes have also been described previously 26,27. The Hind A fragment was isolated by 5% polyacrylamide gel electrophoresis after digestion of IgH701 with HindIII, cleaved with other restriction enzymes and used as substrates of phosphorylation. The restriction sites used for sequencing are indicated in the enlarged map shown below. Ranges and directions of the sequences read are indicated by horizontal arrows I, II and III. Cloned DNA was displayed with the direction of transcription from left to right. M141(MOPC141)^{12,13}, T15(TEPC15)⁸, M603(MOPC603)⁸, IgE1²⁸, MC101^{8,9}, IF-2¹⁰ and J606 (T.N., unpublished data) indicate recombination sites of expressed CH genes in the respective myelomas and hybridoma. A, B, C and D indicate deletion sites in bacteria (see text). Closed boxes indicate coding regions. Horizontal bars a and b show Hind A and 2.6-kb Sau3A fragments, respectively.

site of pBR322 (see restriction map of Fig. 1)¹⁴. The subclone of the 3.7-kb *HindIII* fragment (*Hind A*), which contains the 5'-flanking region of the C_{μ} gene, was used for sequencing. The detailed restriction cleavage map of the *Hind A* fragment was constructed by digestion with combinations of various restriction endonucleases (see Fig. 1) and the nucleotide sequence was determined by the chemical modification method of Maxam and Gilbert¹⁵. The nucleotide sequence determined (Fig. 2) comprises a tandem array of two kinds of pentamer, GAGCT and GGGGT. The length of repeating units varies from 10 to 40 bp depending on the number of GAGCTs per GGGGT.

Because the 2.6-kb Sau 3A fragment of the Hind A fragment (see Fig. 1) does not contain adequate restriction cleavage sites (two MnII sites and abundant AluI, DdeI and HphI sites), we were unable to sequence a core portion of the fragment directly. However, the complete digestion of the Sau3A fragment with AluI, DdeI and HphI provided enough information for us to predict that the Sau3A fragment comprises tandem repetitive sequences similar to those shown in Fig. 2. When the 2.6-kb Sau3A fragment was digested with AluI (AGCT), a major band of 5 bp and a minor 10-bp band were produced in addition to faint bands of 15, 20 and 25 bp (Fig. 3, lanes a, d). The results indicate that the nucleotide sequence of the Sau3A fragment comprises abundant AGCT sequences, probably one every 5 or 10 bp. Obviously, AGCT appears in one of the basic pentamers (GAGCT) of the S_{μ} sequence shown in Fig. 2. Note that the 5-bp fragment was not detectable by ethidium bromide staining (Fig. 3, lane a) but it was clearly shown as the major band among ³²P-labelled fragments (lane d). When the 2.6-kb Sau3A fragment was digested with DdeI (CTNAG), a major band of 5 bp and a minor 15-bp band were produced in addition to faint bands of 20 and 25 bp (Fig. 3, lanes b, e). The results show the presence of a CTNAG sequence every 5 or 15 bp in the Sau3A fragment. CTNAG occurs at the junction of two basic pentamers, (GAGCT)-(GAGCT), in the S_u sequence. Digestion of the Sau3A fragment with HphI (GGTGA) yielded a major band of 20 bp and less intense bands of 15, 25, 30, 35, 40, 45, 50, 55 and 90 bp (Fig. 3, lanes c, f). As GGTGA appears at the junction of two kinds of basic pentamer, (GGGGT)-(GAGCT), in the S_{μ} sequence, the results indicate that GGGGT occurs once every three GAGCTs but that the frequency of GGGGT is rather irregular, ranging up to once every 17 GAGCTs. These results, taken together, indicate that the core portion of the 2.6-kb Sau3A fragment comprises two kinds of pentamer, GAGCT and GGGGT, and that its sequence is represented by $(GAGCT)_n(GGGGT)$. The number n ranges from 1 to 17, with the most frequent value being 3. Thus, the whole S_{μ} region, which lies 1.3-4.8 kb 5' to the C_{μ} gene, consists

Fig. 2 Nucleotide sequence of the S_u region. Nucleotide sequences are displayed from left to right with the direction of transcription of the structural sequence. The sequences are punctuated so that GGGGT is aligned at the same position in each repeating unit. DNA sequence was determined according to the method of Maxam and Gilbert¹⁵ with slight modifications²⁶. DNA fragments to be sequenced were digested with the enzymes indicated in Fig. 1, treated with bacterial alkaline phosphatase (Boehringer) and phosphorylated with T4 polynucleotide kinase (New England Biolabs) and $[\gamma^{-32}P]ATP$ (Amersham). ³²P-labelled DNA fragments were isolated by polyacrylamide gel electrophoresis and cleaved with second restriction enzymes. Fragments labelled only at one end were isolated by polyacrylamide gel electrophoresis and purified as described previously² The regions indicated I, II and III are shown in Fig. 1. Region II was determined using rearranged y3 gene of a γ 3-chain-producing myeloma J606 (unpublished data). Arrow a indicates the recombination site of IF-2¹⁰ while arrows b and c indicate the deletion site of MEP20312

of rather homogeneous repetitive sequences, with GAGCT and GGGGT as basic units.

Dunnick et al. ¹⁰ found repetition of $(GAGCT)_3(GGGGT)$ in the 5'-flanking region of the variant $\gamma 1$ gene of a $\gamma 1$ -chain-producing myeloma, IF2. As this $\gamma 1$ gene has lost a large segment (5.5 kb) of DNA, including the $C_H 1$ domain, a part of the 5'-flanking region of the $C_{\gamma 1}$ gene and portions of the S_μ and $S_{\gamma 1}$ regions, these workers were unable to locate the germ-line origin of $(GAGCT)_3(GGGGT)$ sequence. Nonetheless, they have discussed the possible role of these sequences in the class switch. Comparison of their sequences with ours indicates that the 5' deletion point of the IF2 $\gamma 1$ gene is located in the S_μ region at arrow α shown in Fig. 2 (also see Fig. 1).

In addition to three class switch recombination sites determined previously^{6,8,9,12,13}, we have recently determined two more such sites in the $\gamma 3$ -gene clone isolated from J606 myeloma and the ε-gene clone (IgE1) isolated from IgEproducing hybridoma²⁸ (see Fig. 1). The class switch sites of various classes are ordered as 5'-M141(γ 2b)-T15(α)-Ig ε -1(ε)-MC101(γ 1)-J606(γ 3)-3'. Although these recombination sites tend to cluster at the 5' side of the S_{μ} region, one cannot deduce any physiological significance from this fact because it is possible that a secondary deletion of the S region surrounding the recombination sites occurs during the propagation of myelomas and hybridomas. In fact, the α gene of MOPC603 has an internal deletion within the S_{μ} region⁸. The 5' recombination site in the S_{μ} region was located (see Fig. 1) but the 3'recombination site of the MOPC603 gene, which is the actual class switch recombination site, is not known. Comparison of the nucleotide sequences surrounding each class switch recombination site seems to indicate that H-chain switching is not highly specific to the nucleotides joined (T.N., in preparation). Again, this interpretation is limited if there has been secondary deletion around recombination sites.

We and others have observed that a major portion of the 3.7-kb *Hind* A fragment is deleted during its propagation in *Escherichia coli* ^{4,5,11,12}. Such deletion seems to depend on the

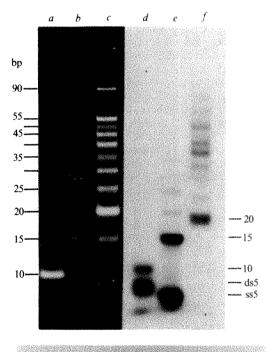

Fig. 3 Digestion of the S_{μ} region with restriction enzymes. $0.6~\mu g$ of 2.6-kb Sau3A fragment was cleaved with AluI~(a), DdeI~(b) or HphI~(c), electrophoresed in 10% polyacrylamide gel and stained with ethidium bromide. The sizes of fragments are shown in base pairs. $0.6~\mu g$ of the 2.6-kb Sau3A fragment was labelled with ^{32}P -dCTP by nick translation 29 and cleaved with AluI~(d), DdeI~(e) or HphI~(f). The sizes of the fragments were determined with pBR322 DNA digested with ThaI or AluI as standard. The 5-bp fragment of DdeI digests ran faster than that of AluI digests, probably because the former has only 2 bp and denatures easily. Nucleotide sequences of restriction sites of the enzymes used are shown at the bottom. ds, Double stranded; ss, single stranded.

host strain; for example, deletion was very frequent in LE392 but rare in C600 regardless of whether they were recA or recA+. The deletion seems to take place at limited sites (indicated by A, B, C and D in Fig. 1). The cloning of the Hind A fragment in pBR322 with a host strain of LE392 has yielded 12 variant clones with inserts of different sizes. The deleted fragment was one of 2.8 kb between sites A and D. 2.3 kb between A and C, 2.4 kb between B and D or 1.9 kb between B and C. Embryonic C_μ-gene clone MEP203¹² deleted the 2.8-kb DNA fragment between arrows b and c in Fig. 2. The nucleotide sequences surrounding the deletion sites of A, B, C and D seem to correspond to the regions containing tandem repetition of regular 20-bp units (Fig. 2).

The S region was originally defined as the functional region responsible for the class switch recombination. We have shown that the structural basis of the S_v region is tandem repetition of homologous 49-bp units⁷. The S_{α} region contains tandem repetition of 80-bp units^{8,9}. It is now clear that tandem repetitive sequences of 20-30-bp units are present in the 5'-flanking region of the C, gene where the class switch recombination occurs. These nucleotide sequences contain abundant short sequences such as GAGCTG and TGGGG which are shared by repeating sequences in the S_{y3} , S_{y1} , S_{y2b} and S_{α} regions as shown in Table 1. It is known that the tandem repetitive sequence increases the chance of homologous recombination¹⁶. Accordingly, the recombination responsible for class switch from μ to α or from one γ to another γ , may be facilitated by such homology of repeating sequences occurring widely in the S region. Tens of short common sequences may be sufficient to make a transient join between two DNAs when they are brought close to each other. As the nucleotide sequences of the repeat units of the S regions are different, it is possible that specific enzymes catalyse the S-S recombination for different pairs of S regions. Both V-J (joining) and S-S recombinations are accompanied by the deletion of intervening DNA segments¹⁷⁻²⁴. We have recently proposed a model in which S-S recombination is mediated by an unequal crossing-over event between sister chromatids9

We thank Drs K. Matsubara and S. Nakanishi for critical reading of the manuscript, and Miss F. Oguni for preparation of the manuscript. This investigation was supported in part by grants from the Ministry of Education, Science and Culture of Japan, Torey Science Foundation, Mitsubishi Science Foundation and Naito Foundation.

Natural killer cells kill tumour cells at a given stage of differentiation

Magnus Gidlund, Anders Örn, Paul K. Pattengale*, Mats Jansson†, Hans Wigzell & Kenneth Nilsson‡

Department of Immunology, University of Uppsala Biomedical Centre, Box 582, S-751 23 Uppsala, Sweden *Department of Pathology, University of Southern California, School of Medicine, Los Angeles, California 90033, USA †Department of Microbiology, University of Uppsala Biomedical Centre, Box 581, S-751 23 Uppsala, Sweden ‡Wallenberg Laboratory, Box 562, S-751 22 Uppsala, Sweden

Natural killer (NK) cells have unique surface features and physiological characteristics and a selective ability to lyse some, but not other, target cells^{1,2}. However, the basis of this selectivity remains obscure at both effector and target cell levels. Proposed specific NK-cell target moieties3-5 include glycolipids, and glycoproteins unrelated to the major histocompatibility complex, while malignant and certain normal cells have been found to be susceptible to NK-cell-mediated cytolysis 6-8. There is good evidence that NK cells can inhibit the outgrowth of small numbers of transplanted tumour cells in vivo 9,10 and can restrict the establishment of secondary metastasis 11,12. It has thus been speculated that NK cells function as a primitive, thymusindependent immune system using phylogenetically preserved target structures to form a cell-mediated resistance barrier against the outgrowth of certain tumour cells1. The presence in the thymuses of neonatal mice and humans^{8,13} and in the marrow of human fetuses, of apparently normal cells which are quite sensitive to NK cells suggested that NK cells might have an increased ability to cause the lysis of cells at a particular stage of their differentiation. In agreement with this concept, embryonal carcinoma cells at various stages of differentiation display a strikingly different susceptibility to NK-cell-induced lysis14. Here only cell types representing early stages were sensitive to NK-cell-mediated cytolysis, whereas the more differentiated endodermal cell lines showed close to complete resistance. The above data would thus support the view that, in vivo, depending on the stage of differentiation, both normal and malignant cells are under surveillance by NK cells. Here we have considered the question of differentiation-related NK-cell susceptibility using defined cell lines known to undergo controlled differentiation in the presence of various agents. Three tumour cell-lines were investigated, and all demonstrated a striking positive correlation between a decrease in NK-cell susceptibility and the induction of differentiation by the various inducers. Our findings support the view that susceptibility to NK-cell mediated lysis may vary according to the stage of differentiation of the target cell.

Table 1 shows the three cell lines used in the present study and the impact of the inducing agents on NK-cell sensitivity in relation to various differentiation markers. The NK-cell sensitivity of K-562, the target cell line most commonly used to assess human NK-cell activity, decreased after exposure to sodium butyrate or haemin. This loss was well correlated in time and dose of the respective inducer with an increase in erythroid differentiation markers such as the expression of surface glycophorin A and haemoglobin synthesis 15. U-937 is a NK-cellsensitive human histiocytic lymphoma cell line16. The phenotype of this cell line suggests that it represents monocytic cells arrested at a differentiation stage close to the myelomonocytic stem cell^{17,18}. Treatment of U-937 cells with either 12-Otetradecanoyl phorbol acetate (TPA) or supernatant from 5-day mixed lymphocyte cultures (MLC) resulted within 2-3 days in the appearance of 30-60% of cells with a macrophage-like phenotype 18-20. Concomitantly, a drastically reduced NKsensitivity profile was noted. K-562 and U-937 show a similar loss of sensitivity regardless of the type of inducer used, demonstrating that 'unrelated' agents giving the same cellular

K-562, a human erythroleukaemia cell line¹², was cultured in RPMI 1640 supplemented with 10% fetal calf serum (FCS) and antibotics. U-937, a 'true' histocytic human cell line¹⁷, was cultured in F10 supplemented as above GM-86 (clone 745), a murine Friend virus-induced leukaemia originating from DBA/2I (ref. 21), was grown in Eagle's medium supplemented with 20% PCS and antibotics. Cells were tested for NK-cell sensitivity using Frcoll-Isopaque-isolated human peripheral blood cells when testing K-562 and U-937, and mouse (CBA/H) spleon cells when analysing GM-86. The sessy used was a 4-h ⁵¹Cr-release test performed in microtitre plates with a fixed number of target cells (10⁴ cells) and various effector cell concentrations as previously described¹⁰, using RPMI 1640 supplemented with 10% newborn calf serum and 10 mM HEPES. Calculations were done accordingly to the formula (c.p m in test—c.p m. in spontaneous control)/(c p m. m detergent—c.p.m. in spontaneous control). Before sessy, target cells were treated as follows. Each tumour cell population was split in half at day 0, one half being cultured in the presence of inducer, the other half serving as control in appropriate media. K-562 cells were treated with sodium buryrate at 1 mM for 3 days to give optimal differentiation²⁰. Haerium was added at 10⁻⁴ M and cells were cultured for 5 days. U-937 cells were cultured in medium supplemented with 20% day-6 supermatant prepared as described elsewhere ^{18,20}. Control cells were cultured in 20% supermatant derived from responder cells alone. Cells were seeded for optimal grown and differentiation at an initial concentration of 3×10⁵ cells ml⁻¹ and further cultured for 3 days²⁰. For TPA treatment cells were seeded at 3×10⁵ cells ml⁻¹ and grown in the presence of 1.6×10⁻⁷ M of TPA for 3 days as described elsewhere ¹⁸. Mouse GM-86 cells were grown in the presence of 4 mM HMBA for 5 days²¹. After induction the cells were washed free of inducer and labelled with ³¹Cr as described elsewhere

alterations also induce a similar increase in NK-cell resistance. Finally, following treatment with hexametabisacetamide (HMBA), GM-86, a mouse Friend virus-transformed erythroid stem cell line²¹, acquired the capacity for globin production. As with the differentiated K-562 and U-937 cell lines, a simultaneous decrease in NK-cell sensitivity was noted.

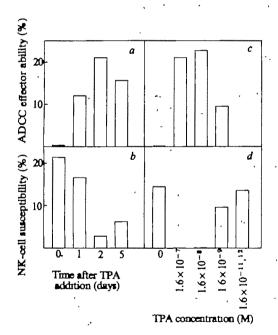

Fig. 1 Time and dose correlation between induced differentiation and loss of NK-cell susceptibility of U-937 cells. a, b, Time correlation. U-937 cells were cultured with TPA as in Table 1 for the indicated period of time. Induction was mitiated at different times to allow simultaneous collection at day 5. After cultivation the cell populations were washed and split. One part was tested for NK-cell susceptibility as in Table 1. The other part was used as effector cells in an ADCC test against antibody-coated chicken red blood cells (CRBC) in a 4-h ³¹Cr-release test in microtitre plates as described elsewhere². A rabbit anti-CRBC lgG fraction was used at 1.2×10⁻⁴ final dilution. Effector target ratio for assaying tumour susceptibility was 50:1 and for ADCC-ability determination 5. 1. Data represent one of two similar experiments. c, d, Dose correlation. U-937 cells were cultured in the indicated concentrations of TPA for 3 days and tested as above. Data represent one of two similar experiments.

Figure 1 shows the strong parallelism seen between the time and dose effect of TPA on U-937 cells with respect to induced differentiation (for other differentiation markers see Table 1), as exemplified by development of the ability to exert antibody-dependent cellular cytotoxicity (ADCC) and by the loss of NK-cell sensitivity. The highest degree of cytotoxic effector potential was found on days 2-3 (Fig. 1a), at which time the tumour cell populations also showed the lowest degree of NK-cell sensitivity (Fig. 1b). Doses of TPA inducing maximal ADCC ability, scored on day 3 (Fig. 1c), similarly produced a highly NK-cell-insensitive cell population (Fig. 1d).

Exposure of BM-86 cells for different periods of time to HMBA, in concentrations inducing optimal erythroid differentiation, resulted in a loss of NK-cell sensitivity (Fig. 2a) which was accompanied by the appearance of globin synthesis as detected by SDS polyacrylamide gel analyses of lysates of GM-86 cells labelled with 35S-methionine in identical conditions (Fig. 2c). In Fig. 2b the same GM-86 cell populations as in Fig. 2a were used as cold target competitors against the well known mouse NK target cell YAC-1 (ref. 6). The time-dependent decrease in NK-cell sensitivity (Fig. 2a) was paralleled by a gradual loss of competing ability. We interpret this to mean that the decreased NK-cell susceptibility of the GM-86 cells after induced differentiation is due to a loss of binding structure(s) for NK cells. However, a similar decrease in competing ability was not seen using differentiated U-937 cells in a parallel system (data not shown). This implies that the differentiation-related alterations seen on the target cell can be expressed either at the level of binding or as a change in susceptibility to lysis. The present system may thus allow the binding and lytic events to be distinguished at the NK target cell level.

The kinetics of the events argue against the possibility that the inducing agents per se cause a decrease in NK-cell sensitivity by some alteration of the target cell, not related to the induced differentiation. This possibility was further reduced by results obtained using spontaneous subclones of K-562 which, as judged by their higher expression of cell-surface glycophorin A, represented a more advanced stage of erythroid differentiation than the original K-562. As Fig. 3a shows, such subclones were also significantly more resistant to NK cytolysis. The clones and original populations could be further differentiated with sodium butyrate to reach the same, still lower, degree of NK-cell sensitivity, inducating the efficiency of the agent in promoting

differentiation to the same final stage in the three different K-562 populations.

To investigate further the correlation between the expression of a differentiation marker and the NK-cell sensitivity profile of cells within a non-cloned tumour cell line, TPA-treated U-937 cells were labelled with fluorescein isothiocvanate (FITC) rabbit anti-human HLA-DR IgG (Fab')2 fragments and sorted on a FACS II cell sorting machine. The population of cells showing markers indicative of greater differentiation (for example, large size and increased expression of HLA-DR¹⁸) were completely resistant to NK-cell lysis (Fig. 3b).

In conclusion, the human K-562 and U-937 cell lines and the mouse GM-86 tumour show a clear correlation between the expression of markers for induced differentiation and reduced NK-cell sensitivity. However, we do not know whether NK-cell sensitivity is always restricted to target cells at an early stage in their respective differentiation. In fact, examples of highly differentiated tumour cells such as myeloma cells, which are quite susceptible to NK lysis¹⁶, the wide variability of NK-cell sensitivity among tumours of the same histogenetic type 10 and the fact that treatment of tumour cells with sodium butyrate can in some cases lead to increased NK-cell sensitivity²⁴, strongly argue against too simplistic a view in this regard. The results do. however, demonstrate that the varying differentiation stages expressed by a particular cell type in a defined differentiation pathway are important in determining NK-cell susceptibility. The availability of the present in vitro systems in which controlled differentiation can be induced significantly increases

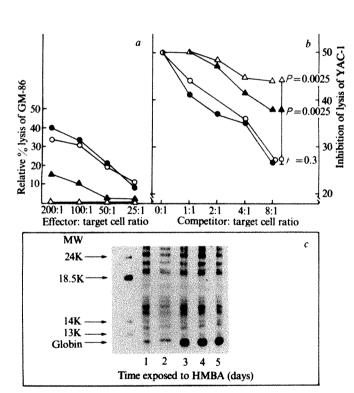

Fig. 2 Induced differentiation in mouse GM-86 cells is accompanied by a loss in NK-cell susceptibility and NK-target competing ability. a, GM-86 cells were cultured with HMBA as in Table 1 for $0 \oplus 0, 2 \oplus 0, 3 \triangleq 0$ and $5 \triangleq 0$ days. The cells were then collected and washed; one part was used as targets for mouse spleen cells as in Table 1, the other part was used (b) as cold competitors against the mouse NK target, the T lymphoma YAC-1, where indicated amounts of cold, unlabelled GM-86 target cells were added to a fixed 1:100 ratio of 51Cr-labelled YAC-1 target to mouse spleen cells to test for lysis as in Table 1. P values were calculated using paired t-statistics making versus day 0 values. c, GM-86 cells grown in identical conditions as in a and b were pulse labelled with 35S-methionine22. The lysates representing each time point were analysed by polyacrylamide gel electrophoresis as described elsewhere²². The globin band was confirmed by immunoprecipitation with a specific rabbit anti-mouse globin antibody (M.J., unpublished). MW, molecular weight.

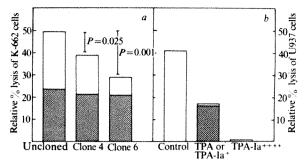

Fig. 3 The reduction in susceptibility of K-562 and U-937 cells is associated with more mature cells. a, Analysis of agarose-cloned K-562 cells. K-562 cells were cloned in agarose and cloned sublines analysed for the expression of surface glycophorin A by immunofluorescence using a rabbit anti-human glycophorin A antiserum (provided by Dr L. Andersson). Sublines expressing the highest amounts of glycophorin A as determined by quantitative cytofluorometric methods²³ were further subcultured. The original K-562 population and its cloned derivatives were tested as NK-cell targets before and after treatment with sodium butyrate (butyrate treatment hatched area) at a 50:1 ratio as in Table 1. Simultaneously the surface expression of glycophorin A was quantitated as described above. The P value after butyrate treatment was >0.5. Data represent one of two similar experiments within a 3-week interval. The P value was calculated as in Fig. 2. b, U-937 cells were induced with TPA as described in Table 1 legend. The cells were then labelled with 51Cr and incubated with an FITC-labelled rabbit F (ab')2 anti-HLA-DR antiserum (provided by Dr L. Klareskog) using phosphate-buffered saline with 0.02% NaN3 for 30 min on ice at a dilution of 1:5. Cells were then washed once in the same buffer and sorted at 4 °C on a FACS II sorter (Becton and Dickinson). Windows were set to obtain the upper 15% of the large, strongly fluorescent cells, denoted TPA-Ia+ giving 6.5×10^4 cells in the right channel. Small cells with insignificant fluorescence were obtained in the left window channel (left channel = $39 \times$ 104 cells), cutting out debris and dead cells (<10% of total). Cells were washed again after sorting, counted, diluted and used as targets in a short-term NK-cell lysis as described in Table 1 legend using a 50:1 effector: target ratio. Control = cells left in culture without TPA and not sorted; TPA = cells induced to differentiate with TPA but not sorted; TPA-Ia++++ = cells induced to differentiate with TPA followed by FACS-II sorting using the right channel. Hatched area = sensitivity of TPA-treated, weak Ia+ cells (left channel, 79% of total TPA cells are TPA-Ia+)

the possibility of analysing fine target structures relevant to NK-cell-mediated cytolysis at the level of binding and/or during the actual lytic event.

We thank Ingela Stadenberg for help with cell cultivation, Dr K. Forsbeck for taking part in the K-562 clone experiments, Dr Fellner for the FACS II sorting and Mrs B. Ehrsson-Lagerqvist for typing the manuscript. This work was supported by grants from the Swedish Cancer Society, NIH (RO1-26752-02) and the Swedish MRC.

Cloned copy of the haemagglutinin gene codes for human influenza antigenic determinants in *E. coli*

Ingeborg Heiland & Mary-Jane Gething

Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, UK

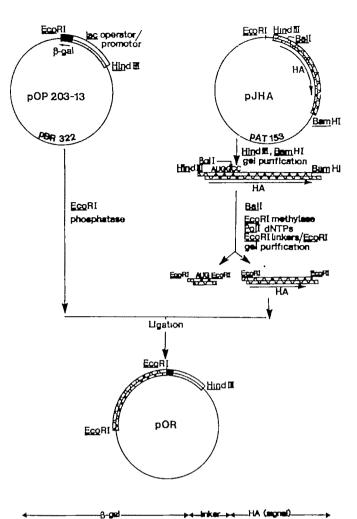

The haemaggintinin (HA) of infinenza virus is the major antigen towards which neutralizing antibodies are directed¹. Epidemics and pandemics of infinenza are associated with variation in the structure of HA^{2,3}. We have recently cloned and sequenced a DNA copy of the RNA gene coding for the HA from human strain A/Japan/305/57 (H2 subtype)^{4,5}. Recent advances in recombinant DNA technology have made it feasible to express in bacteria proteins coded by enkaryotic genes. Viral antigens synthesized in bacteria may ultimately be useful as vaccines. We now report the expression in Escherichia coli of HA antigenic determinants which might be the first approach towards production of a human vaccine. Expression was obtained from the cloned HA gene inserted into a plasmid under the control of the E. coli lac promotor.

Plasmid pJHA⁵ contains a copy of the entire Japan HA gene except for the terminal 11 nucleotides of the 5' non-translated region of the viral RNA. The gene contains an uninterrupted coding sequence specifying a protein of 562 amino acids including the amino-terminal hydrophobic signal peptide of 15 amino acids.

The plasmid pOP203-13 (ref. 6) contains a 203-base pair (bp) DNA sequence consisting of the $E.\ coll\ lac$ UV5 promotor, ribosome-binding site and codons for the first seven amino acids of β -galactosidase. This lac promotor will direct transcription of any DNA fragment inserted into the single EcoRI site of the plasmid (see Fig. 1).

The convenient location of a single Ball restriction site immediately after the AUG start codon in the HA gene⁵ allows the construction of a chimaeric plasmid which should code for a fusion protein consisting of the N-terminal seven amino acids of β -galactoridase followed by the complete HA amino acid sequence. The steps in this construction, together with the N-terminal sequence of the expected fusion protein, are shown in Fig. 1. E. coli HB 101 was transformed with the chimaeric plasmids, and ampicillin-resistant clones containing HA gene sequences were detected by hybridization with 32P-labelled HA DNA7. The orientation of the inserts was determined by restriction enzyme digestions of plasmid DNA isolated from 24 positive clones. In 13 clones the inserts were in the correct orientation for expression with respect to the lac operatorpromotor. Expression of HA antigenic determinants was analysed by solid-phase radioimmunoassay (RIA) using rabbit anti-Japan HA immunoglobulin. As shown in Fig. 2, plasmids pOR4, pOR9 and pOR19 expressed significant amounts of HA antigen.

The nucleotide sequences across the lac-HA juntion were determined for five clones, which are shown in Fig. 3. As was expected, in the three clones (pOR4, pOR9 and pOR19) which were positive in the RIA, the HA DNA was in the correct reading frame for expression. However, they lacked HA gene sequences corresponding to the N-terminal signal peptide and amino acids up to positions 10-15 of the mature protein. Those clones in which the HA DNA was not in the correct reading frame were negative in the RIA. Analysis by restriction enzyme digestion of a further 41 clones which contained the HA insert in

Fig. 1 Construction of expression plasmids. The HradIII-BarnHI DNA fragment of pJHA5 (0.5 µg) was digorted with BelI (restriction enzymes from New England Biolabs, used in the conditions recommended). The EcoRI artes of the DNA were methylated with 0.2 U of S. coh RI methylase (New England Biolaba) for 1 h at 37°C. After phenol extraction and ethanol precipitation, the protrucing ends of the BamHI and HindIII aites were filled using 2U of E. coli DNA polymerase I (Klenow fragment; Boehringer) in a 40-μl reaction volume containing 0.2 mM dNTPx, 60 mM Tru-HClpH 7 5, 8 mM MgCl₂, 1.0 mM 2-mercaptoethanol, 1 mM ATP for 30 min at 10 °C 250 ng ³²P-EcoRI linkers (Collaborative Research; labelled with ³²P-ATP using polynucleotide kmase) in 15 µl of the above buffer were added and ligated to the DNA-using 0 3 U of T4 DNA ligase and 1 U of T4 RNA ligase for 16 h at 9 °C. The buffer was then adjusted to 100 mM Tris-HClpH 7.5, 50 mM NaCl and 5 mM MgCl, and the DNA completely digosted with EcoRL The DNA fragment coding for HA was purified on a 6% acrylamide gel⁴. The plasmid pOP203-13 (200 ng) was digested with *EcoRI* and the 5'-terminal phosphates removed by treatment⁴ with 0.2 U of bacterial alkaline phosphatase in 10 mM Tris-HCl pH 9 5 for 1 h at 37 °C. After phenol and chloroform extractions the DNA was ethanol precipitated and ligated to 50 ng of the HA DNA fragment for 16 h at 10 °C 03 ml CaCl2-treated E. col: HB101 were transfected with the ligated plasmids descrived in 0.2 ml TCM (10 mM CeCl₂, 10 mM MgCl₂, 10 mM Tris-HClpH $7.0)^{17}$ Transformants were selected on agar plates containing $30~\mu g$ ampicallin per ml. These colonies were transferred to introcallulose filters and analysed by in situ hybridization7 using 32P-labelled HA DNA. Positive clones were picked and grown overnight in 10 ml LB proth¹⁸ containing 20 μg ampicillin ml⁻¹ at 37 °C. Mmi-plasmid DNA preparations (1.5-ml cultures) were made up by a modification (lah-Horowicz, personal communication) of the procedure of Birnbolm and Dolyle. Aliquots ($\sim 0.1 \,\mu g$ plasmed) were taken for restriction enzyme discetions to determine the orientation of the inserts. In the HA DNA insert of pJHA there are only two PxtI sites near the 5' end³, so a PxtI digest of the pOR plasmeds with inserts in the correct ementation for expression of HA will give 5,800-, 1,000- and 100-bp fragments whereas those in the wrong orientation will give 4,400-, 2,400- and 100-bp fragments. The resultant fragments were stred on a 1.7% agarose goi (data not shown)

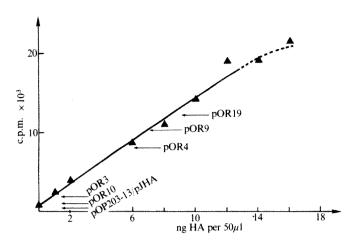

Fig. 2 Radioimmunoassay of HA in lysates of bacteria containing plasmids constructed as described in Fig. 1 legend. Bacterial lysates were prepared and assayed as described elsewhere 10,20. Rabbit anti-HA (IgG) was purified by chromatography on Protein A-Sepharose²¹ and labelled with ¹²⁵I using iodogen as described elsewhere 22. To quantify antigen, a standard curve was constructed using different amounts of purified HA. The results were normalized to the same optical density of cells $(A_{590} = 0.5)$.

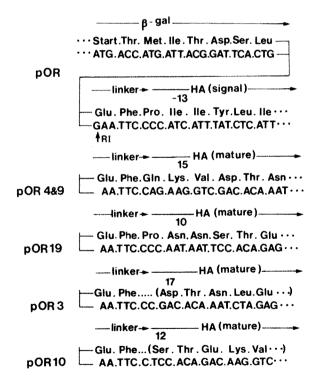

Fig. 3 Nucleotide sequences at the lac-HA junction of plasmids constructed as described in Fig. 1 legend. Only the sequence of the coding strand is given. pOR, expected sequence from the designed construction of plasmid. The nucleotide sequences were determined by the procedures of Maxam and Gilbert⁸. The plasmids were digested with EcoRI, treated with calf intestinal phosphatase (Boehringer) to remove the terminal 5'-phosphates²³ and then radiolabelled with ³²P-ATP using T4 polynucleotide kinase (PL Biochemicals). The fragments from a subsequent restriction digest with AvaI were separated on a 6% acrylamide gel and those containing the HA insertion point were eluted and sequenced.

the correct orientation did not yield any which contained sequences corresponding to the signal peptide or the entire mature HA protein, and showed that in no case had the clones lost any nucleotide sequences corresponding to the C-terminus of the protein. When the construction of the chimaeric plasmid was repeated with the modification that the EcoRI methylation step preceded the Ball digestion, the only clones with the HA insert in the correct orientation with respect to the lac promotor had small insertions at the *lac-HA* junction (results not shown). The reason for the difficulty in obtaining the desired construction is not yet clear. The possibility that the eukaryotic hydrophobic signal sequence of the HA protein is in some way inhibitory or toxic for growth of E. coli is being investigated.

The level of expression in pOR19 corresponds to $\sim 3,000$ molecules of HA per cell. Quantification by RIA assumes that the antigenicity of the hybrid protein synthesized in E. coli is identical with that of the natural HA. This may not be the case as the hybrid protein lacks some amino acids normally at the N-terminus of the mature HA even though they are remote from the major antigenic sites on the molecule9. In addition, the three-dimensional structure of the hybrid protein may differ from that of the natural protein if the correct folding requires transport through a membrane and glycosylation. These factors may affect both the antigenicity and the stability of the bacterially produced protein so that the above estimate of expression level will be a minimum value.

This is the first report of expression of a human influenza HA in bacterial cells. Antigenic determinants of the HA of a related avian orthomyxovirus, fowl plague virus, have been expressed in bacteria using a tryptophan operator/promotor system¹⁰. The level of expression of HA from our plasmid pOR19 is comparable with that of pWT111/FPV502 (ref. 10), although higher levels of expression were obtained after derepression of the trp promotor. The expression level is also comparable with those reported for other eukaryotic genes expressed in E. $coli^{6.11-16}$. As noted previously^{6.10}, the expression levels obtained are considerably lower (< 10%) than those theoretically attainable. It has been suggested that this is due to inefficient transcription, inefficient translation and proteolytic degradation of eukaryotic molecules6.

The HA gene expressed in E. coli does not originate from an influenza strain which is currently causing disease. However, the methods described here are widely applicable and might be a basis for producing a vaccine against a current strain if the levels of expression can be increased.

We thank Forrest Fuller for the gift of plasmid pOP203-13 and Dr John Skehel for rabbit anti-Jap HA serum and purified HA protein. Experiments were performed under conditions recommended by GMAG. This work was carried out during an EMBO long-term fellowship for I.H.

Oestrogen receptor levels and vitellogenin synthesis during development of *Xenopus laevis*

Felicity E. B. May* & John Knowland

Department of Biochemistry, University of Oxford, South Parks Road, Oxford OX1 3QU, UK

The synthesis of vitellogenin, the precursor of the major eggyolk proteins, becomes inducible by oestrogen in *Xenopus laevis* larval liver during metamorphosis¹⁻⁴, well before vitellogenin is required for oocyte growth. The synthesis in pipe of some liver proteins is responsive to oestradioi at earlier stages, but vitellogenin inducibility does not appear until a precise point during metamorphic climax, stage 62, when many 'adult' liver proteins first start to be synthesized. This suggests that vitellogenin inducibility is not determined simply by the presence of an oestrogen receptor. The receptor identified and characterized in fully inducible adult liver 4.7 (also detected by others) is unusual because it is present at very low concentrations and 50% is found in the nucleus in unstimulated animals^{6,7}, and is itself synthesized in response to oestrogen, raising the level in the nucleus'. Here we have measured nuclear receptor levels and the effect of oestrogen on these during Xenopus metamorphosis. Larvae which cannot be induced to synthesize vitellogenin contain an oestrogen receptor with the same affinity and specificity as the adult receptor. Treatment with oestrogen raises the level of nuclear oestrogen receptor in inducible but not in uninducible larvae. These and additional results from thyrostatic larvae suggest that an increase in the level of nuclear receptor is necessary for the induction of vitellogenin synthesis, and that the onset of vitellogenia inducibility might be determined by the ability of oestrogen to increase nuclear receptor

We first measured receptor levels in salt extracts of liver nuclei from untreated and oestrogen-treated larvae at six different stages during metamorphosis, using methods which maximize the yield of soluble receptor from adult liver nuclei, but which would not extract any insoluble receptor. Figure 1 shows examples of the Scatchard plots of total 3H-oestradiol binding for four of the six stages examined. In all cases, the curved Scatchard plots could be resolved into two components10 with the highaffinity component having a dissociation constant close to 0.50 × 10⁻⁹M, the value found previously for the oestrogen receptor in the adult. The relative amounts of low-affinity binding were estimated from the limiting bound/free values, which are proportional to the numbers of non-suppressible binding sites. The relative amounts of receptor and low-affinity binding were very different at different stages and the ratio was affected by oestrogen treatment. For example, the low-affinity component accounted for most of the binding in both untreated and oestrogen-treated stage 54 larvae, but for a much lower proportion in stage 66 animals and an even lower proportion in the same animals after oestrogen treatment. The larval livers were probably contaminated with plasma as it was not practicable to perfuse them; this could account for the often large amounts of low-affinity binding in the nuclear extracts. Neither progesterone, testosterone nor dexamethasone could bind to the larval receptor, and we conclude that the oestrogen receptors of larval and adult liver are indistinguishable by the criteria used here.

Figure 2 shows the number of receptor sites and the relative amounts of low-affinity binding present at various developmental stages. In untreated larvae the amount of receptor increases gradually from 49 sites per nucleus at stage 54 to 74 sites per nucleus at stage 66 (Fig. 2a). This compares with 100 sites per nucleus in the adult male and shows that there is, at the most, a twofold increase in the amount of nuclear receptor between stage 54 and the adult. In contrast, the amount of

low-affinity binding decreased about twofold between stage 54 and 3 months post metamorphosis (Fig. 2b). Vitellogenin synthesis is not inducible in larval liver before stage 62, but is clearly inducible at stage 62 during metamorphic climax, and inducibility increases during the completion of metamorphosis (stages 62–66) and the 3 months following it⁴. This study therefore establishes that the nuclear receptor is present in *Xenopus* liver before vitellogenin synthesis becomes inducible, and shows that the presence of the receptor is not by itself responsible for vitellogenin inducibility.

Figure 2a also shows the levels of nuclear receptor in oestrogen-treated larvae. In the three earliest stages, oestrogen had no effect on the nuclear receptor levels but from stage 62 onwards it progressively increased them, so that by 3 months after metamorphosis the increase in the nuclear receptor level was the same as that found in adult males after oestrogen treatment. Oestradiol treatment did not alter the affinity of the receptor at any stage. The amount of low-affinity binding was

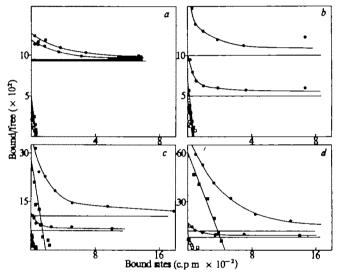

Fig. 1 Affinity of H-contradiol binding in nuclear extracts of liver from untreated or oestrogen-treated Xenopus larvae. All procedures were performed at 0-4 °C. Livers were removed from larvae (staged according to Nieuwkoop and Faber¹³), pooled and washed with saline¹⁴. They were then weighed and 250 mg (equivalent to ~120 hvers) were homogenized in 7 ml of homogenization buffer (0.25 M sucrose, 1 mM Trs-HCl, 1 mM MgCl, $150~\mu g~ml^{-1}$ phenylmethylsulphonylfinoride and 50~mM Bacitracin, pH7.3) using six strokes of a Tedion-glass homogenizer. The homogenate v filtered through two layers of cheesecloth, washed through with another 4 ml of homogenization buffer and centrifuged at 800g for 10 min. The pellet was resuspended in 20 volumes of homogenization buffer and the number of hepatocyte nuclei, which were distinguishable from contaminating crythrocytes, was estimated by microscopic examination of an aliquot. The suspension was recentrifuged at 800g for 10 min and the pellet resuspended in extraction buffer (0.5 M KCl, 0.01 M Tris-HCl, 1 mM 2-mercaptoethanol, 10% glycerol, 150 μg ml⁻¹ phenylmethylmlphonylfluoride and 50 mM Backtracin, pH 7.3) at 2 ml per g of original tissue, frozen and thawed, then homogenized in a small all-glass homogenizer. The nuclear extract was then centuringed in a cooled Beckmann microfuge for 4 min and the supernatant stored in Equal natrogen until use Glass columns (9.5×0 4 cm diameter) ere packed with Sephadex LH-20 which had been swollen in extraction buffer and then equilibrated at 4 °C. To remove endogenous oestrogen, 400 μl of the thawed extract were applied to the columns and cluted with 1 ml of extraction buffer. Abquots of the clustes were incubated with steroid at 20 °C for 1 h to allow exchange of bound steroid with "H-oestrachol". 100 µl were applied to each column and eluted with 750 µl extraction buffer. Eluates were counted with 50% efficiency after extraction of radioactivity into scintillant (10 ml containing. PPO (diphenyloxazole), 4 g; POPOP (p-phenylenephenyloxazole), 0.1 g per litre of tolinene) Equilibrium bindmg constants were estimated from the binding curves. We plotted the total binding to ³H-cestradiol according to Scatchard¹⁵ and determined the hmiting bound/free ratio reached after the high-affinity component becomes saturated. This ratio was used to calculate the low-affinity binding at each free ligand concentration, this was subtracted from the total binding to give the binding due to the high-affinity component, which was then analysed according to Scatchard 13 to give the K_a and number of binding sites. To study the effect of oestrogen, larvae were immersed for 3 days in 1 µM oestradiol in water, which was renewed daily, before staging them and removing their livers. The total H-oestradiol binding was determined at various concentrations of ³H-contradiol in untreated (O) or contragon-treated (O) larvae and the high-affinity binding assayed in untreated () or costrogen-treated

(III) livers (as described above) at stage 54 (a), 57 (b), 62 (c) or 66 (d).

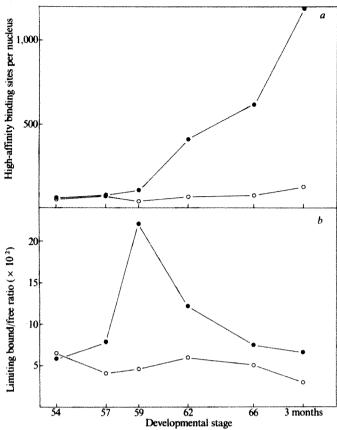

Fig. 2 Average number of high-affinity oestrogen-binding sites per nucleus (a) and the limiting bound/free ratio (b) as a measure of low-affinity binding in Xenopus liver during metamorphosis. At least two measurements were made at each stage. ○, Untreated and ●, oestrogen-treated larvae.

also increased by oestrogen treatment, but here the increase was greatest at the onset of metamorphic climax (stage 59) and much lower at later stages, being only twofold at stage 66. In contrast, the amount of nuclear oestrogen receptor was first increased by oestrogen treatment at stage 62, when vitellogenin synthesis becomes inducible. This suggests that the ability of oestrogen to induce vitellogenin synthesis at a certain stage during development is closely connected with its ability to increase receptor levels. We examined this relationship in further experiments.

An important advantage of developmental studies on Xenopus is that larval development can be arrested in late premetamorphosis using compounds such as propylthiouracil (PTU). As these animals age, events which would occur if they were developing normally will take place only if they do not depend on metamorphic development. This has allowed us to show⁵ that only half the alterations in liver protein synthesis normally associated with metamorphosis are dependent on developmental stage rather than on chronological age. If two events which occur during development retain the same temporal association in developmentally arrested animals, additional evidence is provided that one event requires the occurrence of the other. We therefore measured the level of oestrogen receptor and the effect of oestrogen on this level in liver from developmentally arrested larvae. The animals were first kept for 1 yr in water containing 10 µg ml⁻¹ (0.58 mM) PTU, which was changed every 2 weeks. This arrested development at stage 54, but did not inhibit growth, so that at the time of use the thyrostatic larvae were considerably larger than normal larvae of the same developmental stage. Vitellogenin synthesis was uninducible in the stage 54 thyrostatic animals, but Fig. 3 shows that there was as much receptor (100 sites per nucleus) in the livers of these larvae as in adult males, confirming that receptor alone cannot confer inducibility. Figure 3 also shows that the level could not be increased by oestrogen treatment, so that in this respect the thyrostatic larvae at stage 54 behaved like normal larvae of the same stage. The amount of low-affinity binding was somewhat higher in arrested larvae and was increased about twofold by oestrogen treatment whereas in normal larvae oestrogen had no effect on the amount of lowaffinity binding.

Animals were then removed from PTU and allowed to metamorphose, and the nuclear oestrogen binding was measured at various stages during this delayed metamorphosis (Fig. 3), before and after treatment with oestrogen. Whereas the level of induction of the low-affinity binding decreased (Fig. 3b), the nuclear receptor levels were increased by oestrogen treatment from about stage 60 (Fig. 3a), the stage at which vitellogenin synthesis becomes inducible in these animals⁴. The increased level of the receptor in stage 62 animals which had previously been kept in PTU was about the same as in normal animals of a similar stage (Fig. 2a). In all cases the dissociation constant of the receptor found in larvae that had been treated with PTU was $0.50 \pm 0.05 \times 10^{-9}$ M, the value found for normal larvae.

These results show that while the normal, small rise in receptor content to the level found in adult males does not require metamorphosis, the ability of oestrogen to increase receptor levels does. In addition, in both normal and arrested animals oestrogen can first increase the level of nuclear receptor at the developmental stage when it can first induce vitellogenin synthesis. This precise correlation suggests that an increase in the level of nuclear oestrogen receptor is required for the induction of vitellogenin synthesis, and that the ability of oestrogen to increase the level of its receptor is in some way responsible for the appearance of vitellogenin inducibility. These data are consistent with results from other steroidresponsive systems^{11,12} where the rate of accumulation of the steroid-induced protein and its mRNA is thought to be determined by the level of nuclear receptor. In these systems the increase in nuclear receptor levels after hormone treatment is largely the result of translocation from a pre-existing pool of cytoplasmic receptor whereas in Xenopus liver it is probably due to synthesis of the receptor9. We have previously described5 a

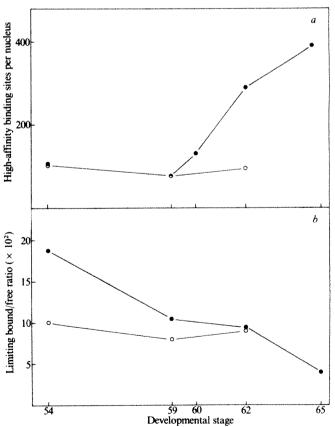

Fig. 3 Number of high-affinity oestrogen-binding sites per nucleus (a) and the limiting bound/free ratio (b) as a measure of the low-affinity binding in the livers of thyrostatic or previously thyrostatic Xenopus larvae.

O. Untreated and \bullet , oestrogen-treated larvae.

set of cellular proteins whose synthesis is influenced by oestrogen in larval liver before stage 62. Our data show that an elevated level of liver nuclear oestrogen receptor is not induced by oestrogen in animals of this stage. A model has been proposed11,12 in which different levels of nuclear oestrogen receptor are required to induce transcription of different genes, perhaps reflecting different affinities or numbers of nuclear acceptor sites, and our results are consistent with this type of model.

Mycoplasmas induce collagenase in BALB/c 3T3 cells

Barbara Kluve*, William C. Merrick*, Eric J. Stanbridge† & Howard Gershman*‡

*Department of Biochemistry, Case Western Reserve University, School of Medicine, Cleveland, Ohio 44106, USA †Department of Microbiology, University of California, Irvine, College of Medicine, Irvine, California 92717, USA

The turnover of collagen, the major protein of the body, is controlled by the rate of collagen synthesis and the activity of collagenase, a highly specific protease which initiates collagen degradation. Because collagen is largely resistant to other proteases, collagenase is believed to have an important regulatory role in such normal processes as tissue remodelling, wound healing and ageing. In addition, the regulation of the activity of collagenase may be altered in diseases of connective tissue, particularly rheumatoid arthritis, and in malignant invasion and metastasis. Collagenase is an extracellular enzyme, and thus it has been necessary to study its regulation in cells maintained in tissue culture, by measuring accumulation of the secreted protein in the culture medium. In this way, collagenases have been isolated from many tissues and cells1-7. Little is known about the modulation of collagenase synthesis and secretion, but various treatments have been reported that induce its secretion in mammalian cells in monolayer culture⁸⁻¹⁷, possibly by a possibly by a mechanism involving membrane perturbation. We report here the production and secretion of collagenase by BALB/c 3T3 fibroblasts. Their ability to synthesize collagen 18,19 has been extensively studied, but there has been no previous report of their collagenolytic activity. During studies of collagenase activity in BALB/c 3T3 cells, we noted that certain cultures had greatly increased enzyme activity corresponding to cultures in which contamination with mycoplasmas had been detected during routine assay. Here we present evidence that infection of cultures of BALB/c 3T3 cells with mycoplasmas results in the accumulation of high levels of collagenase in the medium.

Figure 1 shows the time course of accumulation of collagenase activity in the culture medium of BALB/c3T3 cells known to be infected with mycoplasmas. Replicate cultures of BALB/c 3T3 cells were established and allowed to achieve confluence. Then the culture medium was changed and this point was taken as day 0 of culture. On each successive day from 1 to 9, the medium from duplicate dishes was collected and assayed for collagenase activity as described in Fig. 1 legend. Collagenase activity began to accumulate in the medium at about day 2, increased rapidly for the next 2 days, and then began to decline slowly. We do not know whether this decrease in accumulated collagenase activity is due entirely to an increase in rate of inactivation that eventually exceeds the rate of synthesis, or whether the rates of synthesis and secretion also decline. No collagenase activity was detected in medium not treated with trypsin; all the collagenase secreted was therefore in an inactive form. In addition, cell homogenates had no detectable collagenase activity, either active or trypsin-activable, indicating that most or all of the collagenase synthesized by 3T3 cells is secreted into the medium. Cell numbers did not, within experimental error, change in the period of collagenase accumulation (during the first 4 days after medium change), in uninfected, newly infected or chronically mycoplasma-infected cultures. Cell densities in infected and uninfected cultures were similar at confluence and throughout the period of collagenase production.

The contaminating microorganism in the 3T3 cultures with high collagenolytic activity was identified as Mycoplasma orale on the basis of a growth inhibition test using dried antiserumimpregnated disks20. The induction of collagenolytic activity in cultures of BALB/c 3T3 cells by infection with mycoplasmas was demonstrated by adding an aliquot of pure mycoplasma culture, obtained as described above, to uninfected cells, which had low but measurable activity. The time course of the appearance of collagenolytic activity in these newly infected cultures is shown in Fig. 2. In this experiment confluent cultures

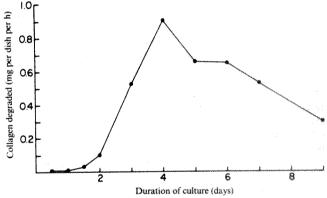

Fig. 1 Accumulation of collagenase activity in medium of BALB/c 3T3 cultures. BALB/c 3T3 cells were grown in Eagle's minimum essential medium (Gibco) with fourfold increased concentrations of vitamins and amino acids (Gibco) plus 10% fetal calf serum (Gibco), 100 U ml-1 penicillin and 100 µg ml-1 streptomycin (Sigma). The cells were plated into 10-cm plastic tissue culture dishes (Costar) containing 15 ml of medium. After the cells reached confluence, the medium in all dishes was replaced with fresh medium (day 0), and the cells maintained in these media for the time indicated. Media were collected from replicate cultures at the times indicated, centrifuged to remove debris, and brought to 0.1 M Tris-HCl, pH 7.5, and 0.05% sodium azide. Collagenase was precipitated from the conditioned medium by the addition of ammonium sulphate to 60% saturation. The precipitated protein was dissolved in, and dialysed against 0.05 M Tris-HCl, pH 7.5, 0.01 M CaCl₂, 0.05 M NaCl and 0.05% sodium azide. A 15-fold concentration of the starting volume was consistently achieved. All samples were then assayed for collagenase by measuring the release of soluble peptides from native collagen fibrils reconstituted at 37 °C (ref. 27). Each reaction mixture contained 36 µg of ¹⁴C-collagen in 10 µl of 0.1 M Tris-HCl, pH 7.5, 0.1 M NaCl, 0.01 M CaCl₂ and 0.05% sodium azide. The collagen had been radiolabelled by in vitro methylation to a specific activity of 667 c.p.m. per µg. A 30-µl aliquot of the collagenase preparation was added to the gelled collagen and treated with 30 µg of trypsin (Sigma no. T-1005) at room temperature for 45 min to activate the collagenase. A fourfold excess of soybean trypsin inhibitor (Sigma) was then added. Replicate reactions were incubated for increasing times at 37 °C and were terminated by centrifugation at 8,000g for 10 min. The entire supernatant fraction containing the digested collagen was counted in a liquid scintillation spectrometer. Blanks, which contained the same additions, including trypsin and trypsin inhibitor but no collagenase, were also run for each time of assay. Radioactivities released in these control reactions, which was generally less than 5% of the experimental (collagenase-containing) samples, were subtracted from the data shown. Units of collagenase activity were determined from the linear portion of each rate curve. Identical results were obtained in samples activated by dialysis against 1 mM APMA at 4 °C, in place of trypsin treatment.

were established as described in Fig. 1 legend and the medium replaced with 15 ml of fresh medium to which was added 0.45 ml of a broth culture containing mycoplasmas. Control cultures received only fresh medium. Subsequently, the media were collected every 4 days and replaced by 15 ml of fresh medium. The media were assayed for collagenase activity as described in Fig. 1 legend.

As shown in Fig. 2, uninfected cells secreted relatively low levels of collagenase activity during each of the 4-day collection periods, whereas newly infected cells secreted increasing amounts of collagenase with time after infection. During the first 4 days, medium collected from both newly infected and control cultures had equivalent collagenase activity. However, during the second 4-day period, cultures infected with samples of mycoplasmas contained substantially increased collagenase activity. Medium from these infected cultures collected during the third 4-day period showed even higher collagenase activity, equal to that produced by cultures that had been infected before the start of the experiment (also shown in Fig. 2) and in which the level of collagenase activity had stabilized. In addition, parallel uninfected cultures received 0.45 ml of medium from infected 3T3 cultures instead of pure cultures of mycoplasmas. Collagenase activity in these cultures, also shown in Fig. 2, increased with a time course similar to that of the cultures treated with pure mycoplasmas. The increased level of collagenase activity in the third collection of medium from control cultures may be due to stimulation by accumulated collagen in the cultures; these cells are known to secrete and deposit collagen, which has been recently reported to stimulate the synthesis and secretion of collagenase8. On subculture, the level of collagenase in the control (uninfected) cell cultures dropped to the original level, while those in infected cultures remained high. The levels of collagenase that accumulate in culture medium exposed for 4 days to mycoplasma-infected cells are ~ 4.3 U per 10^6 cells (1 U = 1 µg collagen degraded per min at 37 °C). Uninfected (control) 3T3 cells produce < 0.25 U per 106 cells. This is similar to the unstimulated/stimulated levels calculated from data reported for human skin fibroblasts exposed to collagen (0.36/7.14 U per 106 cells; see ref. 8), for rabbit corneal cells stimulated by lymphocytes from alkaliburned animals (0.7/6.1 U per 10⁶ cells; ref. 16) and for human synovial fibroblasts stimulated by cytochalasin B (0.64-1.6/7.7-7.1 U per 10⁶ cells; ref. 12).

The various cultures used in the experiment shown in Fig. 2, were re-examined for the presence of mycoplasmas. The control

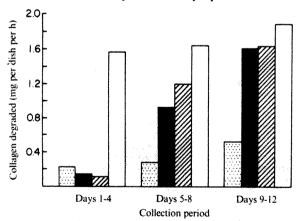

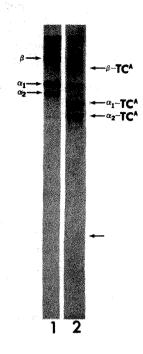

Fig. 2 Induction of collagenase activity in BALB/c 3T3 cultures after infection with mycoplasmas. BALB/c 3T3 cells were grown as described in Fig. 1 legend. After the cells reached confluence, the medium in all dishes was replaced with fresh medium (day 0). At this time, duplicate cultures received 0.45 ml of fresh medium (stippled bars); 0.45 ml of medium from infected BALB/c 3T3 cultures (solid bars); or 0.45 ml of a broth culture of mycoplasmas (cross-hatched bars). Parallel cultures of BALB/c 3T3 cells were grown in which mycoplasma infection had been previously established (open bars). Media were collected from each of these cultures every 4 days over a 12-day period and replaced with fresh media. After collection, the media were centrifuged to remove debris and brought to 0.05 M Tris-HCl, p H 7.5, and 0.05% sodium azide. Collagenase was measured as described in Fig. 1 legend.

Fig. 3 SDS-polyacrylamide gel electrophoresis of collagen after reaction with BALB/c 3T3 collagenase. Lane 1. 24 μg of ¹⁴C-collagen before incubation with collagenase. Lane 2, 24 µg 14Ccollagen incubated with partially purified collagenase at 23 °C for 24 h. The reaction mixture contained 12 µg of partially purified collagenase and 24 µg of ¹⁴C-collagen in a solution consisting of 0.05 M Tris-HCl, pH 7.5, 0.01 M CaCl₂, 0.05 M NaCl, 1 mM phenylmethylsulphonyl fluoride, 0.04% sodium azide and 6.25% glycerol in a final volume of 32 µl. The collagenase used was purified by precipitation with (NH₄)₂SO₄ (40-60% saturation), batch elution from phosphocellulose, gradient clution from QAE-Sephadex A-50, gradient elution from phosphocellulose. and gel filtration on Sephadex G-100. The collagen had been radiolabelled by in vitro methylation28 to a specific activity of 667 c.p.m. per µg. The reaction was stopped by the addition of icecold 10% trichloroacetic acid. The protein was allowed to precipitate and then collected by centrifugation at 8,000g for 15 min. The protein pellet was rinsed twice with acetone, dried and dissolved in 20 µl of electrophoresis sample buffer containing 10% glycerol, 0.1 M dithiothreitol, 2% SDS, 0.08 M Tris-HCl, pH 6.8, and 0.2% bromophenol

blue. The sample was heated to 95 °C for 5 min then subjected to SDS-polyacrylamide gel electrophoresis (0.1% SDS in 12% polyacrylamide) according to the method of Laemmli²⁹. The gels were stained with Coomassie blue, dried and autoradiographed using Kodak X-Omat R film. The figure shows the autoradiograms of these gels. In lane 1, the positions of the $\alpha_1\beta$ -dimer, α_1 and α_2 are indicated. In lane 2, almost all the β -dimer, as well as most of the α_1 and α_2 polypeptides, have been digested. The positions of β -TC^{Δ}, the large cleavage product of β , and α_1 -TC^{Δ} and α_2 -TC^{Δ}, the large cleavage products of α_1 and α_2 are indicated. The unlabelled arrow indicates the position of TC^{Δ}, which can be visualized by overexposing the autoradiogram or by incubating reaction mixtures with collagenase for shorter times.

cultures contained no detectable mycoplasmas, whereas the remaining three cultures, all of which showed increased collagenolytic activity, were infected. We have therefore concluded that infection of BALB/c 3T3 cells with mycoplasmas results in the increased accumulation of extracellular collagenase.

The collagenase produced by cultures of BALB/c 3T3 cells infected with M. orale seems to be a product of the murine 3T3 line, rather than that of the mycoplasma. We base this conclusion on the following evidence. (1) BALB/c 3T3 cells produce collagenase, although at a much lower level, before infection. (2) Mycoplasma organisms in broth, or transferred to culture medium in dishes containing no 3T3 cells, demonstrated no collagenase activity when assayed in the same conditions as BALB/c 3T3 culture medium. (3) We have partially purified the enzyme and found it to be similar to previously reported mammalian collagenases. Briefly, it degrades collagen at neutral pH; in crude preparations it requires treatment with trypsin or p-aminophenylmercuric acetate (APMA) for maximal activity; and it is completely inhibited by EGTA, orthophenanthroline and serum, partially inhibited by cysteine and dithiothreitol, and not inhibited by phenylmethylsulphonyl fluoride or soybean trypsin inhibitor. Most significantly, and in direct contrast to bacterial collagenases, collagenase purified from culture medium of mycoplasma-infected BALB/c 3T3 cleaves collagen into characteristic three-quarter length TCA and one-quarter TCB fragments, as shown in Fig. 3.

Thus, it seems that BALB/c 3T3 cells can synthesize and secrete relatively low levels of collagenase in normal circumstances. Infection of BALB/c 3T3 cells with mycoplasmas results in a significant increase in the accumulation of collagenase in the culture medium. Infected cultures of confluent cells show uniformly high levels of collagenase activity even after subculturing. In addition, the ability of mycoplasmas

to induce the synthesis and/or secretion of collagenase is not limited to BALB/c 3T3 cells. We have shown that cultures of chick fibroblasts also give dramatic increases in the level of extracellular collagenase activity on infection with mycoplasmas (data not shown). The induction of collagenolytic activity in cells by infection with mycoplasmas may have important clinical implications in terms of the development and persistence of connective tissue diseases. Mycoplasmas are recognized as agents possibly contributing to the establishment of rheumatoid arthritis in humans21,22 and are known to cause chronic arthritis

in certain animal species23; increased levels of collagenase have been associated with joint destruction in rheumatoid24,25 and osteoarthritic26 conditions. It seems reasonable to hypothesize that the involvement of mycoplasmas in disease states stems, at least in part, from their induction of collagenase.

Two distinct candidate transforming genes of lymphoid leukosis virus-induced neoplasms

Geoffrey M. Cooper* & Paul E. Neiman†

* Sidney Farber Cancer Institute and Department of Pathology, Harvard Medical School, Boston, Massachusetts 02115, USA † The Fred Hutchinson Cancer Research Center, Seattle, Washington 98104, USA

Avian lymphoid leukosis viruses (LLVs) are oncogenic retroviruses which induce tumours with relatively long latent periods and which seem to lack viral transforming genes1. We previously reported that high molecular weight DNAs of seven LLV induced tumours efficiently transformed NIH 3T3 mouse cells on transfection and that the transformed NIH cells did not contain viral DNA sequences detectable by hybridization with probes homologous either to the entire LLV genome or to the long terminal redundancy (LTR) of LLV DNA². These results suggested that oncogenesis by LLVs involved indirect activation of cellular transforming gene(s) which were not linked to LLV DNA. Hayward et al. recently found that 80-90% of LLVinduced metastatic bursal lymphomas contained exogenous LTR sequences near the cellular gene (c-myc) homologous to the presumptive transforming gene of myelocytomatosis virus strain MC29, a highly oncogenic avian acute leukaemia virus. Integration of LTR sequences containing the viral transcriptional promoter apparently increases transcription of c-myc in these lymphomas3. We now report that the LLV-induced tumours used as donors of DNA in our previous transfection experiments also contain LTR sequences near c-myc. However, further analysis of the NIH cells transformed by DNAs of LLV-induced bursal neoplasms indicates that transformation was not mediated by transfer of the tumour c-myc gene. These observations suggest that at least two different cellular genes with potential oncogenic activity are activated by different mechanisms in LLV-induced neoplasms.

DNAs of LLV-induced tumours were digested with EcoRI, electrophoresed in agarose gels, transferred to nitrocellulose filters and hybridized to 32P-DNA probes for either the 5' LTR sequences of LLV DNA (p53-5' probe) or for the chicken c-myc gene (pmyc probe, a gift of C. Pachl and M. Groudine) (Fig. 1).

32P-DNA of pmyc hybridized to two EcoRI fragments of normal chicken DNA with molecular sizes of ~14 and ~20 kilobases (kb) (Fig. 1). The 14-kb EcoRI fragment of normal chicken DNA is similar to the c-myc-containing EcoRI fragment4 and appears to contain all the chicken c-myc sequences. In addition to the 14- and 20-kb EcoRI fragments of normal chicken DNA, ³²P-DNA of pmyc hybridized to a tumour-specific EcoRI fragment in DNAs of two neoplastic bursal nodules (T^c and T^d 2993), a metastatic bursal lymphoma (2902) and a nephroblastoma (3000) (Fig. 1). In each case, the tumour-specific c-myc-containing EcoRI fragment also hybridized to p53-5' probe (Fig. 1). Similar results were obtained with DNAs of a second metastatic lymphoma (B7362) and of a cell line derived from such a lymphoma (RP9) (not shown).

These observations are consistent with the findings of Hayward et al.3. As an EcoRI site is present within the LTR of exogenous LLVs5,6, integration of an LTR near chicken c-myc in the tumour DNAs results in formation of a tumour-specific EcoRI fragment containing both 5' LTR and c-myc sequences.

EcoRI-digested DNAs of NIH cells2 transformed by DNAs of the lymphoma cell line RP-9, metastatic lymphoma B7362, bursal nodule Td 2993 and bursal nodule 2999 were hybridized to pmyc probe to determine whether the transformed NIH cells contained c-myc sequences derived from the tumour DNAs (Fig. 2). The c-myc-containing EcoRI fragment of 14 kb was readily detectable in normal chicken DNA, which was included as a positive control. In contrast, c-myc sequences were not detected in NIH cells transformed by LLV-induced tumour DNAs. Although we have detected normal mouse sequences homologous to chicken c-myc as faintly hybridizing EcoRI fragments of ~10 kb in NIH 3T3 DNA, these bands are too faint for photographic reproduction. The absence of chicken c-myc sequences in NIH cells transformed by LLV-induced tumour DNAs indicates that the transforming gene of these tumours detected by transfection is different from the c-myc gene activated in the tumours by integration of LTR sequences.

LLV-induced tumours thus appear to contain at least two different genes with potential oncogenic activity: a c-myc gene activated by integration of a viral LTR and a distinct cellular gene capable of efficiently transforming NIH 3T3 cells. As both genes are present in most or all LLV-induced tumours so far studied^{2,3}, including a nephroblastoma, premetastatic bursal nodules and metastatic bursal lymphomas, it would seem that both genes are important in LLV-induced oncogenesis.

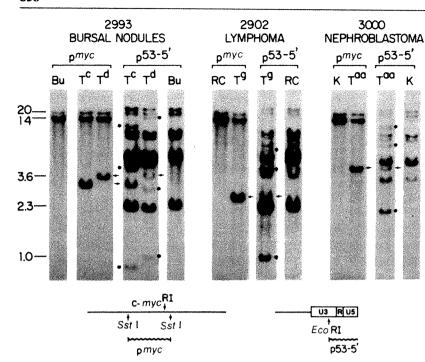

Fig. 1 Analysis of LLV-induced tumour DNAs. EcoRI-digested DNAs (10 μg) from two discrete bursal nodules $(\breve{T}^c \text{ and } T^d)$ and surrounding normal bursa (Bu)from bird no. 2993, from a metastatic bursal lymphoma (T8) and erythrocytes (RC) from bird no. 2902, and from a small nephroblastoma (Taa) and normal kidney from bird 3000 were subjected to agarose gel electrophoresis and Southern blot hybridization using ³²P-DNA probes prepared by nick-translation of pmyc and p53-5', pmyc contains a 3.2-kb Sstl fragment which was subcloned in a derivative of pBR322 containing a single Sst1 site from a bacteriophage λ clone of c-myc isolated from the λ library of random chicken DNA fragments prepared by Dodgson et al. 10, p53-5' was a fragment of p5311 and contains the sequences (165 bp) from the EcoRI site in viral LTR to the terminus of linear LLV DNA. Tumour-specific fragments which contain both c-myc and p53-5' sequences are indicated by arrows. Additional tumour-specific fragments containing p53-5 sequences are indicated by circles. Molecular sizes (kb) are indicated for the normal chicken DNA fragments detected with pmyc probe (14 and 20 kb) and for the internal EcoRI fragments of LLV DNA detected previously¹² with probes representative of the entire LLV genome (1.0, 2.3 and 3.6 kb).

Activated cellular transforming genes which are not linked to viral DNA have also been detected by transfection of DNAs of mammary carcinomas induced by mouse mammary tumour virus which, like LLV, induces tumours with long latent periods and does not appear to contain a viral transforming gene7.

The pathogenesis of LLV-induced lymphomas suggests a multi-step process probably involving more than a single transformation event8. Activation of c-myc may therefore be involved in a stage of tumour development which precedes or complements activation of the transforming genes detected by transfection. Further studies will be required to define the roles of these two potential transforming genes in the disease.

We thank M. Groudine and C. Pachl for the c-myc clone, W. Hayward and S. Astrin for communicating their results before publication, and D. Macdonnell and S. Okenquist for technical assistance. These studies were supported by NCI grants CA21082, CA20068 and CA28151.

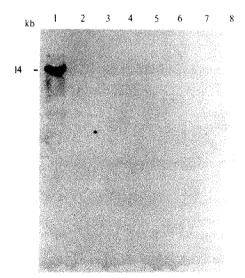

Fig. 2 Absence of chicken c-myc sequences in transformed NIH cells. EcoRI-digested DNAs (20 µg) of normal chicken embryo fibroblasts (lane 1), NIH 3T3 cells (lane 2), two independent lines of NIH cells transformed by DNA of bursal nodule Td 2993 (lanes 3 and 4), two independent lines of NIH cells transformed by DNA of bursal nodule 2999 (lanes 5 and 6), NIH cells transformed by DNA of metastatic bursal lymphoma B7362 (lane 7) and NIH cells transformed by DNA of lymphoma cell line RP9 (lane 8) were analysed by blot hybridization with pmyc probe.

A tryptophan-containing peptide recognizes and cleaves DNA at apurinic sites

Tula Behmoaras, Jean-Jacques Toulmé & Claude Hélène

Laboratoire de Biophysique, INSERM U201, Muséum National d'Histoire Naturelle, 61, Rue Buffon, 75005 Paris, France

Oligopeptides containing aromatic amino acids can preferentially form stacked complexes with single-stranded nucleic acids^{1,2}. Moreover, the peptide lysyl-tryptophyl- α -lysine (Lys-Trp-Lys) binds efficiently to locally destabilized regions in DNA after UV irradiation^{3,4} or modification by N-acetoxy-N(2)-acetylaminofluorene⁵. Lys-Trp-Lys also photosensitizes the cleavage of pyrimidine dimers in DNA³. We have recently shown that removal of purines in DNA introduces strong binding sites for this tripeptide through very efficient stacking of the tryptophyl residue with nucleic acid bases at apurinic sites⁶. We report here that incubation of partly depurinated DNA with Lys-Trp-Lys results in a specific cleavage of the DNA backbone probably due to the presence of the amino groups brought by the peptide into close proximity with the apurinic sites. This could provide a model for the enzymatic activity of AP endonucleases which are involved in the first step of the in vivo repair of apurinic site-containing DNA7.8.

The binding of the peptide Lys-Trp-Lys (P) to nucleic acids (N) involves the formation of two complexes C1 and C2 according to a two-step model proposed earlier1:

$$P+N \stackrel{\kappa_1}{\Longrightarrow} C_1 \stackrel{\kappa_2}{\Longrightarrow} C_2$$

The tryptophyl ring of the peptide is stacked with nucleic acid bases in complex C₂ whereas only electrostatic interactions occur in complex C1. With a DNA containing apurinic sites the value of K_2 , which measures the ratio of the concentrations of stacked and unstacked complexes, is much higher than for any form of DNA damage previously studied^{3,6}. The values of K_2 for a native and an apurinic site are 0.3 and =200, respectively⁶. Because of the high value of K_2 and the unmodified value of K_1 (ref. 6), the overall association constant $[K_1 (1+K_2)]$ is more than two orders of magnitude higher for an apurinic site than for a native site. The peptide Lys-Trp-Lys can therefore recognize apurinic sites in a double-stranded structure through stacking interactions. The tryptophyl ring occupies the vacant site left by the removal of a purine6

To test the ability of Lys-Trp-Lys to cleave the DNA backbone at apurinic sites, an average of two purines were removed from supercoiled covalently closed PM2 DNA molecules (see Fig. 1 legend and ref. 9). Cleavage of one strand per DNA molecule converts the supercoiled DNA (form I) into the relaxed form (form II). As the electrophoretic mobilities of these two forms are different, agarose gel electrophoresis can be used to visualize single-strand breaks. Incubation of PM₂ DNA containing two apurinic sites in the presence of Lys-Trp-Lys resulted in a decrease in the intensity of the band corresponding to form I and a simultaneous increase in the intensity of the band corresponding to form II (results not shown). This effect was not

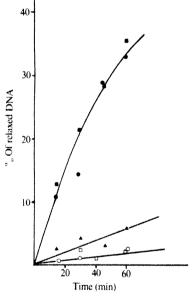

Fig. 1 Kinetics of single-strand break production in closed supercoiled PM2 DNA containing two apurinic sites on incubation at 37 °C with Lys-Trp-Lys (●), Lys-Tyr-Lys (■), Lys-Gly-Lys (▲) or alone in the same conditions (control, 0). PM2 DNA without apurinic sites was also incubated with Lys-Trp-Lys (□). PM2 DNA containing 70% supercoiled molecules was incubated for 8 min at 70 °C in 0.1 MNaCl, 10 mM phosphate, 10 mM citrate (pH 5) to introduce about two apurinic sites per molecule9. These DNA samples were precipitated with ethanol and redissolved in 1 mM NaCl, 0.2 mM EDTA and 1 mM sodium cacodylate (pH 6). 10 µl of 10^{-4} M peptide solutions were added to $10 \,\mu l$ of 2×10^{-4} M DNA substrate at 37 °C. After the indicated time the solutions were withdrawn and diluted with 6 µl of a solution containing 50% glycerol and 0.1% bromophenol blue. The mixtures were loaded onto 0.8% agarose gels and the gels stained with ethidium bromide. Agarose gels were photographed and negatives were scanned with a spectrodensitometer. The ratio of relaxed and supercoiled DNA was estimated from the areas under the corresponding peaks.

observed when native DNA without apurinic sites incubated with the peptide, indicating that the cleavage is related to the presence of apurinic sites in DNA. The amount of relaxed DNA molecules increased with the time of incubation: 35% of supercoiled DNA was cleaved after 60 min at 37 °C (Fig. 1). In the absence of Lys-Trp-Lys, incubation at 37 °C had a negligible effect on DNA containing apurinic sites (Fig. 1), whereas 1 h incubation of apurinic DNA with the peptide Lys-Gly-Lys resulted in the conversion of only 6% supercoiled DNA containing two apurinic sites to open DNA. The endonucleolytic activity is therefore clearly related to the specificity conferred to Lys-Trp-Lys by stacking interactions between the indole ring and nucleic acid bases, with the indole ring replacing the missing purine⁶. A tyrosine-containing peptide, Lys-Tyr-Lys, exhibited the same catalytic activity as Lys-Trp-Lys (Fig. 1), providing indirect evidence that the tyrosyl residue does stack with nucleic acid bases at apurinic sites.

Curves similar to those shown in Fig. 1 were obtained using fluorescence emission of intercalated ethidium bromide as a probe10. Intercalation of ethidium bromide molecules is favoured in relaxed relative to supercoiled DNA¹⁰. The ethidium bromide fluorescence emission was higher for apurinic DNA samples incubated with Lys-Trp-Lys than for DNA alone or for DNA incubated in the presence of Lys-Gly-Lys (results not shown). The time dependence of ethidium bromide fluorescence enhancement was similar to that of cleavage measured by gel electrophoresis.

The presence of an aromatic amino acid residue brings amino groups of lysyl residues into the vicinity of apurinic sites. At an apurinic site in DNA, the deoxyribose residue occurs in equilibrium between the free aldehyde and the furanose forms11, and the previously reported effects of amines on the rate of chain cleavage probably depend on an interaction with these aldehydic groups¹². The present data suggest that the specific binding of Lys-Trp-Lys to apurinic sites enhances the local amine concentration. The different amines investigated by Lindahl and Andersson which promoted chain breakage at apurinic sites in DNA were added at 10⁴-fold higher concentrations than those used with Lys-Trp-Lys¹²

The mechanism of Lys-Trp-Lys-induced strand breakage is unknown. Cleavage could involve the formation of a Schiff base between the aldehydic group of the ribosyl moiety at apurinic sites and an amino group of the peptide and/or a β -elimination reaction, as has been proposed for the cross-linking of histones to DNA after methylation followed by depurination¹³. To locate the NH₂ group involved in cleavage we are now investigating the activity of peptides in which the indole ring is separated from the potential 'active site' by glycyl residues (results to be reported elsewhere).

Our results show that the peptide Lys-Trp-Lys mimics both the damage specificity and the catalytic activity of endonucleases specific for apurinic sites (AP endonucleases). Stacking interactions provide a simple tripeptide with the essential recognition specificity required for this activity.

Sequence specificity of methylation in higher plant DNA

Yosef Gruenbaum, Tally Naveh-Many, Howard Cedar & Aharon Razin

Department of Cellular Biochemistry, The Hebrew University-Hadassah Medical School, Jerusalem, Israel 91010

Although plant DNA has a high content of 5-methylcytosine (5mC¹) very little is known about the distribution of this modification. Many of these methylations are found in the dinucleotide sequence C-G (refs 2-5) which is also the major modified site in animal cell DNA. It is clear, however, that C-G methylation cannot account for all the 5mC in DNA, in which this modified base may represent over 30% of the cytosine residues (as in certain varieties of plant¹). It was this observation that prompted the search for other methylated sites in the DNA. The results presented here show that methylated cytosine is indeed present at a variety of cytosine-containing dinucleotides, all of which, however, are part of the basic trinucleotide C-X-G. This sequence is probably essential for modification as it provides the symmetrical cytosines necessary for ensuring the inheritance of methylation at these sites.

The first step in characterizing plant DNA methylation was to determine the dinucleotide distribution of all the 5mC present in this organism. This was achieved by a modification of the standard nearest neighbour analysis which allows the detection of 5mC⁶. Plant DNA contains 5mC at C-A, C-T and C-C as well as C-G sites and the extent of methylation at these sequences is summarized in Table 1 (all sequences are in the $5' \rightarrow 3'$ direction). In lieu of the nearest neighbour frequencies for this DNA⁷, the methylation observed in Table 1 accounts for the total methylcytosine of wheat-germ DNA, $\sim 23-29\%$ of all cytosines¹. Similar results were obtained for 2-week seedling wheat DNA and for other higher plant varieties, including tobacco.

Studies on the inheritance of 5mC in animal cells stongly suggest that the symmetrical presence of 5mC on both strands of the DNA is necessary to ensure the inheritance of this modification, at least at the sequence C-G. Because none of the dinucleotides C-A, C-T or C-C can accommodate this type of symmetry, we postulated that methylation at these sites might be based on a trinucleotide symmetry at the sequence C-X-G. This hypothesis is supported by the nearest-neighbour analyses for C-A and C-T (see Table 1), as it predicts that these dinucleotides

will be found in the sequence $\frac{C-A-G}{G-T-C}$ and would therefore be

methylated to the same extent. To examine this possibility, we developed an extension of the nearest-neighbour analysis technique which allows the detection of methylation at specific cytosine containing trinucleotide sequences. As shown in Table 1, over 80% of the trinucleotide sequences C-T-G and C-A-G were found to be modified, whereas the non-symmetrical sequence C-A-T was less than 4% methylated.

These partial sequence data strongly suggest that most, if not all, of the methylated C-A and C-T sequences in plant DNA are found adjacent to G in the prototype symmetrical trinucleotide

 $\begin{cal}C-A-G\\G-T-C\end{cal}$ To validate this observation, we searched for restriction

enzymes which might recognize this site and be sensitive to cytosine methylation. Several restriction enzymes have recognition sequences which contain the sequence C-G but do not cleave when this site is methylated, for example, *HpaII*, *HhaI* and *AvaI* which have been used to analyse the methylation pattern of total mammalian DNA as well as specific genes^{8,9}. As expected, both *HpaII* and *HhaI* cleave plant DNA very poorly (data not shown). Individual restriction enzymes may be useful for detecting methylation at other sites. *Eco* RII, and *PstI* have

recognition sequences containing the trinucleotide sequence C-A-G, but do not cleave when cytosine is methylated¹⁰. As

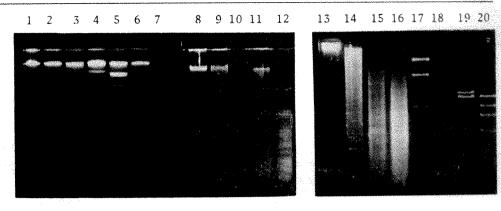

shown in Fig. 1, wheat-germ and tobacco DNA are very poorly digested by these three enzymes, all of which digest animal DNA as expected. To determine the extent of methylation at these and other restriction sites, it was necessary to quantitate the degree of DNA digestion. To this end, the average molecular size of the

Table 1 Nearest-neighbour analysis of 5mC in plant DNA

DNA sequence	% Methylation	
C-G	82	
C-A	19	
C-T	19	
C-C	7	
C-A-G	>80	
C-T-G	>80	
C-A-T	<4	

DNA from wheat-germ was prepared as follows. Frozen wheat germ was ground under liquid nitrogen by mortar and pestle. The powder was dissolved in a mixture containing 10 mM Tris-HClpH 7.9, 0.4 M NaCl, 5 mM EDTA, 0.5% SDS and 100 μg ml⁻¹ proteinase K (Merck), incubated for 1 h at 37 °C, extracted three times with phenol followed by three extractions with chloroform/isoamyl alcohol (24:1 v/v) and ethanol precipitated. The DNA preparation was treated for 30 min with RNase A and further extracted with phenol and chloroform/isoamyl alcohol. The plant DNA (5 µg) was randomly nicked by sonication and nick translated with E. coli polymerase I (Biolabs) in the presence of a single $[\alpha^{-32}P]$ -deoxynucleoside triphosphate (200–500 Ci mmol⁻¹, NEN)⁶. The $[\alpha^{-32}P]$ -labelled DNA was digested to deoxynucleoside 3' monophosphates using micrococcal nuclease and spleen phosphodiesterase and applied to thin layer cellulose sheets (Eastman Kodak). The nucleotides were separated by two-dimensional chromatography and analysed by autoradiography as previously described⁶. Following TLC, the cytosine and 5-methylcytosine spots were scraped from the plastic sheet and the amount of radioactivity in each was determined by liquid scintillation counting. The percentage of cytosine methylation for each dinucleotide was then calculated $[(C/5mC+C)\times$ 100]. In each case the nearest-neighbour frequencies of other dinucleotides appearing on the chromatogram were also measured to ensure that these correspond to published data on nearest-neighbour analyses. Partial trinucleotide sequencing was performed using the same basic technique modified to select specific trinucleotide sequences. DNA was nick translated in the presence of a single nucleotide as described above using either $[\alpha^{32}P]dATP$ or $[\alpha^{32}P]dTTP$. Following a 5-min incubation at 15 °C, ddATP, ddCTP and ddTTP were added (6 mM each) and the reaction was continued for an additional 30 min. After this treatment only sequences containing Xp*TpG or Xp*ApG will have a free 3'-OH group. The DNA was isolated by phenol extraction, Sephadex column chromatography and ethanol precipitation. This DNA was denatured and those molecules containing a free 3'-OH end were elongated with poly(dA) tails using 18 units terminal transferase (PL Biochemicals). The specific molecules which contained the desired labelled trinucleotide sequence were then isolated by oligo(dT) cellulose chromatography²⁰. This DNA was then subjected to nearest-neighbour analysis⁹. Whereas ~20% of the C-A or C-T residues in plant DNA were found to be methylated, >80% of the trinucleotide sequence C-T-G and C-A-G were modified. In keeping with this, the DNA which did not stick to the oligo(dT) column and therefore did not contain poly(A) tails was only 5% methylated. This, of course, would include DNA containing all Cp*A and Cp*T residues which are not adjacent to G. For the C-A-T triplet, the procedure was modified slightly by using the dideoxynucleotides ddATP, ddGTP and ddCTP and the standard deoxynucleotide dTTP to select the correct sequence. The results are expressed as the percentage of methylation of the cytosine present in each sequence and should be considered as reliable estimates of the methylation content. The values shown for these triplets were obtained from the chromatogram and adjusted to take into account the instances where the second nucleotide is repeated. Thus, in addition to C-A-G the sequences C-A-A-G and C-A-A-G will also be selected by the oligo(dT) column and therefore contaminate the desired triplet. As indicated in Table 1, the values represent minimal estimates because these data have not been corrected for the fact that the dideoxynucleotide triphosphates are not 100% efficient even at the high concentration used in this experiment (unpublished results).

Fig. 1 Detection of plant DNA methylation by restriction enzyme analysis. DNA was prepared as described in Table 1 legend and digested by various restriction enzymes at a ratio of 2 units per ug DNA for 2 h using the buffers and conditions recommended by the suppliers. Restricted DNA was separated by electrophoresis on 1.5% (lanes 1-12) or 1.8% (lanes 13-20) agarose (Seakem) gels stained with ethidium bromide and photographed using Polaroid positive-negative type 665 film. Undigested tobacco DNA (lane 1) and undigested wheat-germ DNA (lanes 8 and 13) are shown for comparison. Tobacco DNA was cleaved with Pst I (lane 2), PvuII (lane 3), Eco RII (lane 6) and Bst NI (lane 7). Tobacco DNA was also digested with

Pst I (lane 4) and Pvu II (lane 5) in the presence of the marker λ phage DNA. Wheat-germ DNA was cleaved with EcoRII (lane 9), BstNI (lane 10), MspI (lane 14), HaeIII (lane 15) and Taq I (lane 16). This DNA was also digested with EcoRII (lane 11) and BstNI (lane 12) in the presence of the marker herpes simplex virus DNA. Lanes 17-20 contain molecular weight markers (250-4,500 bp) obtained by restriction digestion of various plasmid and phage DNAs.

DNA resulting from each restriction enzyme digestion was calculated from optical density scans of the ethidium bromidestained agarose gels. The average experimental length of DNA obtained for each restriction enzyme can then be compared with the expected size computed on the basis of nearest-neighbour frequencies. For the enzymes HpaII and HhaI the experimental length is 10 times greater than expected, indicating that this site is $\sim 90\%$ methylated in wheat-germ DNA. The restriction sites for PstI, PvuII and EcoRII were also found to be extensively methylated (Table 2). Note that the degree of methylation at PstI and PvuII sites represents an underestimate, because the average size of the DNA resulting from these digestions is probably higher, but not within the range of sensitivity for this particular gel. In the case of EcoRII the decreased digestion cannot be due to a lack of sites for this enzyme, because Bst NI, an isoschizomer of EcoRII that cleaves even if cytosine is methylated, cleaves this DNA normally (Fig. 1, Table 2).

In addition to methylation at C-A, C-T and C-G dinucleotides, we observed a small amount of methylation at C-C. It is tempting to suggest that these methylations are also localized in the trinucleotide site $\frac{C-C-G}{G-G-C}$. One might expect that both

cytosines could be methylated in this sequence, as the internal cytosine is part of a C-G dinucleotide. The enzyme *MspI* (C-C-G-G), which is inhibited by methylation at the external cytosine¹⁰, may be useful for probing methylation at C-C-G sites. The average expected molecular size of plant DNA after digestion with *Msp I* is 440 base pairs (bp). As shown in Fig. 1 and Table 2, the average size of DNA resulting from *MspI* digestion is over twice that expected, suggesting that the external cytosine of this site is about 50% methylated.

BstNI may be used to visualize directly the extent of methylation at $\frac{C-A-G}{G-T-C}$ sequences. As this enzyme cleaves the pentanucleotide sequence $CC \stackrel{\downarrow}{T} GG$ on the 3' side of the inter-

nal C, restriction digestion leaves DNA tails consisting of one nucleotide, A or T. These tails may be labelled with $[\alpha^{-32}P]$ dATP or $[\alpha^{-32}P]$ dTTP using the large subunit of *Escherichia coli* DNA polymerase I. When this DNA is subjected to nearestneighbour analysis, the labelled phosphate is transferred to the internal C of the EcoRII sequence. If this cytosine is methylated, it should be revealed by chromatographic analysis of the 3'-monophosphate nucleotides. Autoradiography clearly shows that cytosine is the only labelled nucleoside phosphate, and that it is extensively methylated (90%) (Fig. 2). This experiment

provides direct evidence that this particular site is highly methylated and suggests that other ${C \cdot A \cdot G \over G \cdot T \cdot C}$ sites are similarly

modified. Because the cytosine residues adjacent to both A and T are 90% methylated, we also conclude that this site is symmetrically methylated on both DNA strands.

In animal cells 5mC accounts for about 2-7% of the total cytosine¹¹, whereas over 25% of the cytosine residues are methylated in plant cells¹. This difference is due to two major factors. Although in both plants and animals the C-G sequences are methylated to about 70-80%, the C-G dinucleotide is much more frequent in Plant DNA (3-4%) than animal DNA (0.5-1%)⁷. The second element which contributes to the high 5mC content of plants is methylation at other sites. Partial sequence analysis and restriction enzyme studies clearly show that almost all methylated C-A, C-C and C-T residues are found in the symmetrical trinucleotide sequence C-X-G.

It has previously been noted that C-G is a dinucleotide which contains symmetrical cytosine residues in both strands of the DNA and other evidence suggests that when this dinucleotide is modified both cytosines are indeed methylated^{9,12}. This symmetry is probably what enables the cell to transmit its methyl-

Wheat-germ or mouse liver DNA was digested with various restriction enzymes at a ratio of 2 enzyme units per µg DNA for 2 h in the specific buffers recommended by the enzyme manufacturers (New England Biolabs, Bethesda Research Laboratories and Boehringer-Mannheim). The restricted DNA (5-10 μg) was subjected to gel electrophoresis on 0.6% agarose (HpaII, EcoRII, BstNI, PstI, PvuII), 1.5% agarose (MspI, BstNI) or 1.8% agarose (MspI, TaqI, BstNI, HaeIII). Each gel was run together with at least 20 molecular length marker bands obtained by restriction enzyme digestion of various plasmid and phage molecules. Following electrophoresis, the ethidium bromidestained gels were photographed using positive-negative Polaroid film and the film negative assayed using a scanning spectrophotometer. The resulting graphs were computer digitalized and the average molecular size calculated by reference to the molecular weight markers20 results were then corrected to take into consideration the size of the undigested DNA which was of the order of 50 kilobases. These results are accurate to about ±10%. Expected average molecular size of each restriction enzyme was calculated from nearest-neighbour data. The per cent methylation at each of these sites was determined by comparing the experimental and the expected size.

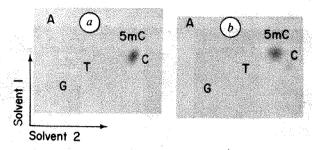

Fig. 2 The extent of methylation of the sequence CC_TAGG in wheat-germ

DNA. DNA (5 μ g), prepared as described in Table 1 legend, was cleaved with 10 units of BstNI for 60 min at 60 °C. The DNA fragments were labelled at their 3' end by filling the sticky ends using E. coli DNA polymerase I (large fragment) with either $[\alpha^{32}P]dATP(a)$ or $[\alpha^{32}P]dTTP(b)$ for 10 min at 37 °C (ref. 21). The labelled fragments were digested to deoxynucleoside 3' monophosphates, chromatographed by two-dimensional TLC and autoradiographed6.

ation pattern to succeeding generations. In general, replicating DNA is in a state of hemimethylation since the parental strand is methylated at specific sites, which the newly replicated strand is as yet unmodified. The cellular 'maintenance methylase' would then act on the new strand using the parental strand methylation pattern as template 11,13-15. This model has received recent support from experiments in which unmethylated and in vitro methylated DNA were introduced into mouse L-cells by DNAmediated gene transfer. Whereas unmethylated DNA remains unmodified, methylated foreign DNA faithfully inherits its in vitro acquired methylated pattern16,17. We propose that the same symmetry that characterizes the dinucleotide C-G must be an integral part of any inheritable methylated residue. All the methylated sequences in plants seem to fit this criterion, as all methylations are either at the dinucleotide sequence C-G or the symmetrical trinucleotide sequence C-X-G.

The site ${C\text{-}C\text{-}G}\atop{G\text{-}G\text{-}C}$ may be methylated at either of two different

cytosines or at both. In either event, the single cytosine on the complementary strand would have to serve as a template for both cytosine methylations. The fact that this single methylated cytosine is part of a C-G residue suggests that in such cases the internal cytosine on the C-C-G strand will always be methylated, but the external cytosine may or may not be modified. This was indeed found to be the case for Scilla satellite DNAs analysed for methylation by DNA sequencing⁵. Methylation at the external cytosine of the trinucleotide C-C-G raises problems with regard to the inheritance of this methylation. As the complementary strand used as a template during replication contains only one methylated cytosine in the sequence C-C-G, it is difficult to understand how the methylase decides whether or not to methylate the external cytosine in addition to the internal cytosine. This decision may be random or determined by adjacent DNA sequences. Note that two specific C-C-G-G sites in the human globin gene battery were found to be resistant to MspI and therefore methylated at the external cytosine in a tissue-specific manner^{18,19}. Because, in general, vertebrate DNA does not contain a detectable amount of C-C methylations, this type of animal DNA methylation is probably very rare.

As in vertebrate cells, the methylatable sites of plant DNA are not fully methylated. Approximately 80% of all C-G or ${\buildrel C-A-G}$ sites are methylated and only 50% of the C-C-G sites are modified at the external cytosine. It is this incomplete methylation which makes these sites potential factors in cellular regulation. A large body of evidence supports the view that DNA methylation may indeed play a part in the control of vertebrate gene expression. It is tempting to speculate that both the methylated C-G and C-X-G sites may also be involved in the regulation of gene expression in higher plants, but there is no evidence to support this. The enzymes PstI, PvuII and EcoRII

should prove useful for studying the relationship between gene expression and methylation in plant cells.

We thank Dr U. Lavi for tobacco DNA and Dr S. Ben-Sasson for helpful discussions. This work was supported by NIH grant GM 20843 and Israel-US, Binational Science Foundation grant

The acetylcholine receptor (AChR) mediates synaptic transmission on binding to the acetylcholine neurotransmitter. To gain further information on the composition and biosynthesis of this receptor (for review of properties see refs 1-3), we have extracted AChR mRNA and translated it in a cell-free system and also in Xenopus oocytes. The latter have been shown to be not only highly efficient translation systems for microinjected, heterologous mRNAs but they can also faithfully execute posttranslational processes such as glycosylation, sequestration, prepeptide cleavage and secretion of appropriate products⁴⁻⁷. As native AChR is found glycosylated and sequestered in the plasma membrane, this system is of potential interest in studying its biosynthesis. We report here that Xenopus oocytes efficiently assemble intact, multi-subunit AChR molecules which show properties characteristic of the native AChR, including the binding of α -bungarotoxin (α -BTX).

Initially, cell-free translation⁸ products of mRNA extracted from the electric organ of the ray, Torpedo marmorata, were immunoprecipitated with rabbit antiserum raised against the native AChR. AChR-specific polypeptides with apparent molecular weights (MWs) of 40,000 (40 K), 51 K and 59 K were clearly identified; two smaller and less abundant species were also found (Fig. 1). These sizes differ from those of the subunits thought to comprise native AChR1-3; unlike the latter, the cell-free translation products were unable to bind α -BTX, which agrees with previous work9. Thus, the cell-free system seems to be incapable of faithfully synthesizing intact receptor molecules.

Experiments in which Torpedo mRNA was injected into Xenopus oocytes gave better results. Figure 2 shows that

^{*} Present address; Celitech Ltd. 250 Bath Road, Slough, Berkshire, SL1 4DY, UK

 α -BTX binding activity could be detected in the translation products of the oocytes, the actual level of activity increasing with the amount of heterologous mRNA injected. To characterize the α -BTX binding component, ³⁵S-methionine-labelled translation products were purified by affinity chromatography on α -BTX-Sepharose (for details see Fig. 3 legend), and analysed by SDS-polyacrylamide gel electrophoresis ¹⁰ (Fig. 3b, lane 1). As a control for nonspecific binding to the Sepharose, an aliquot of the extract was preincubated with a large excess of α -BTX before chromatography and electrophoresis (Fig. 3b,

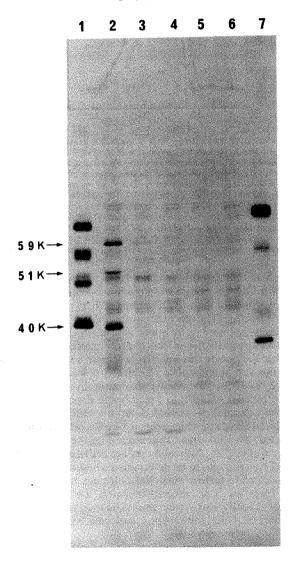

Fig. 1 Electrophoretic analysis of AChR polypeptides synthesized in a cell-free system. Poly(A) mRNA (25 µg ml⁻¹) extracted from the electric organ of Torpedo marmorata 16 was translated in a nuclease-treated rabbit reticulocyte lysate8 in the presence of 35S-methionine (~1 mCi ml-1). The translation products were immunoprecipitated using formalin-fixed Staphylococcus aureus cells (SAC)¹³. The SAC antibody-antigen complexes were dissolved in SDS sample buffer ¹⁰ and SAC removed by centrifugation at 10,000g for 1 min. The supernatants were electrophoresed through a 10% (w/v) SDS-polyacrylamide gel10 before fluorography17. Lane 1, AChR purified from T. marmorata electric organ by affinity chromatography then radioactively-labelled with succinimidyl [2,3-3H]propionate11. radiolabelling process gives the appearance of doublets after gel electrophoresis, which are absent in non-radioactive purified preparations of the native AChR (see Fig. 3a). Lane 2, immunoprecipitate obtained with antibody raised against native Torpedo AChR. Lane 3, immunoprecipitate obtained with antibody raised against native Torpedo AChR but in the presence of a large excess of native Torpedo AChR; control for lane 2. Lane 4, immunoprecipitate obtained with normal rabbit serum; lane 5, immunoprecipitate produced with antibody against α-BTX (control for lane 6). Lane 6, immunoprecipitate obtained by pre-incubating with α -BTX, before addition of antibody raised against α -BTX. Lane 7, ¹²⁵I-labelled standard proteins-bovine serum albumin (68 K), catalase (58 K), ovalbumin (43 K) and lactate dehydrogenase (35 K). Titres of antibody raised against native Torpedo AChR and α -BTX were $\sim 2 \times 10^{-6}$ M and $\sim 4 \times 10^{-6}$ M, respectively.

lane 2). Lanes 1 and 2 of Fig. 3b show four toxin-specific polypeptides of MWs 40 K, 49 K, 58 K and 66 K; these sizes are very similar to those of the native Torpedo AChR polypeptides that had been purified by α -toxin-gel affinity chromatography and then radioactively labelled by H-propionylation (Fig. 3b, lane 3). The native subunit sizes (Fig. 3a) were estimated to be 40 K, 49 K, 57 K and 65 K, as generally found for the α , β , γ and δ subunits heart similar electrophoresis pattern was also obtained when oocyte translation products were purified by binding to α -BTX, followed by immunoprecipitation with α -BTX antibody and protein A¹³.

The size of the AChR molecule synthesized in oocytes was analysed by centrifugation through sucrose density gradients. As Fig. 4 shows, the AChR purified from the Torpedo electric organ exists in two molecular forms having sedimentation coefficients of 9S and 13S (monomer and dimer), an observation generally made 1-3 for Torpedo AChR preparations, the 9S form being predominant in reducing conditions. The monomeric 9S form has been shown^{2,3,12} to contain five subunits $(\alpha_2, \beta, \gamma, \delta)$, corresponding to a MW of ~250,000. It was therefore interesting that on a parallel sucrose density gradient (Fig. 4), the translation products from the microinjected oocytes produced a peak of toxin-binding activity at the same position (9S) as the native monomer. This result clearly indicates the ability of the oocyte to assemble the newly synthesized subunits into intact receptor molecules. After sedimentation of 35S-methioninelabelled translation products and immunoprecipitation of these gradient fractions with the antiserum raised against native AChR, SDS-gel electrophoresis showed that the receptorspecific peptides were present only in the 9S peak (data not shown). Assuming that this antibody can recognize newly synthesized, unassembled AChR polypeptides, which is the

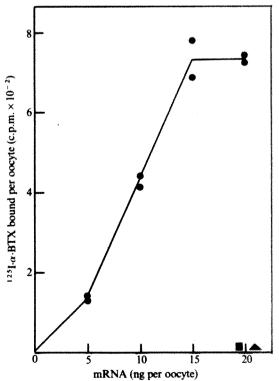

Fig. 2 α-BTX binding activity in Xenopus oocytes after microinjection with Torpedo mRNA. Duplicate batches of 15 oocytes were microinjected⁵ with various amounts of poly(A) mRNA that had been extracted¹⁶ from the electric organ of T. marmorata and cultured at 21 °C in 150 μl modified Barths' medium⁵ for 48 h. The oocytes were then homogenized in 200 μl of 50 mM phosphate buffer, pH 7.2/1% Triton X-100/1 mM EDTA/1 mM EGTA/0.1 mM phenylmethylsulphonyl fluoride (PMSF). The 1251-α-BTX¹⁸ binding activity (♠) in the resulting supernatants was measured¹⁹ after centrifugation at 10,000g for 30 min. ♠, Control in which a large excess of unlabelled α-BTX was added just before the assay. ♠, As for experimental sample except that before the assay, the extract was incubated with Con A-Sepharose²⁰.

likely interpretation of the data from the cell-free system (see Fig. 1 and ref. 9), it seems that the assembly process in oocytes is efficient.

As in the case of the native Torpedo receptor 12,14, the AChR synthesized in microinjected oocytes is also glycosylated, as it binds completely to concanavalin A(ConA)-Sepharose (Fig. 2). The y-subunit synthesized in oocytes may be slightly larger than that in the purified native AChR, thus it is possible that glycosylation and/or other processing events in the oocyte are not

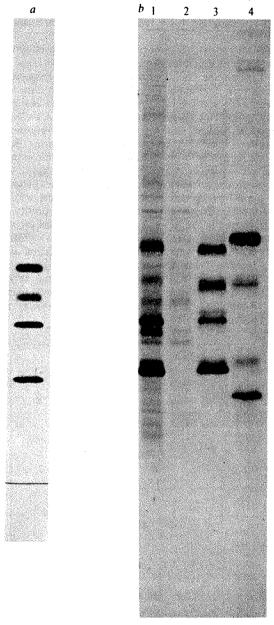

Fig. 3 Electrophoretic analysis of the AChR synthesized in oocytes as purified by affinity chromatography on α -BTX-Sepharose. a, A stained gel containing nonradioactive AChR purified from T. marmorata 11 . (Note that this gel is shorter than that in b.) b, Batches of 40 oocytes were microinjected with *Torpedo* poly(A) mRNA (20 ng per oocyte) and cultured in 300 μl Barths' medium containing 0.3 mCi ³⁵S-methionine at 21 °C for 48 h. They were then homogenized in 500 µl of 50 mM phosphate buffer, pH 7.2/1% Triton X-100/1 mM EDTA/1 mM EGTA/5 µg ml-1 soybean trypsin inhibitor/1 mM benzamidine/100 µg ml-1 bacitracin/0.1 mM PMSF, centrifuged at 10,000g for 30 min. The supernatant was shaken with 0.1 ml α -BTX-Sepharose, which was then washed 11 . All purifications were done as rapidly as possible in the cold and in the presence of protease inhibitors to limit proteolysis¹¹. Lane 1, AChR was eluted from the α -BTX-Sepharose using $50 \,\mu$ l of 2% SDS in sample buffer¹⁰, and 25 μ l electrophoresed. Lane 2, a control preparation containing the same ³⁵S-labelled translation products, preincubated with a large excess of α-BTX before application to α -BTX-Sepharose. Lane 3, 3 H-propionylated native *Torpedo* AChR (see Fig. 1). Lane 4, 125 I-labelled standard proteins (see Fig. 1). A 10% (w/v) SDS-polyacrylamide gel 10 was used; b was subjected to fluorography 17 and ato silver staining2

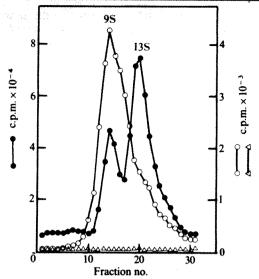

Fig. 4 Analysis of the molecular form of the AChR newly synthesized in oocytes. 40-50 oocytes were microinjected with 20 ng of mRNA per oocyte and cultured for 48 h. The oocytes were then extracted in 200 µl buffer as described in Fig. 2 legend. Samples of oocyte extracts or of AChR purified from *T. marmorata* were loaded on to 5-20% (w/w) sucrose gradients containing 50 mM phosphate buffer, pH 7.2/100 mM NaCl/0.2% Triton X-100/1 mM EDTA/0.02% NaN₃ and centrifuged in a Beckman SW60 Ti rotor at 59,000 r.p.m. for 6 h (ref. 11). Fractions (0.13 ml) were collected by upward displacement and analysed for α-BTX binding activity using 125 I-α-BTX as described in Fig. 2 legend. , Purified AChR from Torpedo; A, extract from uninjected oocytes; O, extract from oocytes injected with Torpedo mRNA

completely faithful for this product. However, when detergent (Triton X-100) was omitted from the homogenization medium (Fig. 2), over 90% of the α -BTX binding activity remained in the membrane fraction. The receptor molecule is transported in vivo to the plasma membrane by a mechanism which shares many common features with the process of protein secretion 15. As it is known that the oocyte can selectively secrete a wide variety of homologous and heterologous proteins^{6,7}, it seems likely from the above result that the oocyte also faithfully sequesters the newly synthesized AChR into a membrane structure.

Thus the heterologous mRNA determines the production of multi-subunit receptors which seem to be efficiently synthesized, glycosylated, assembled and sequestered by the oocyte with a high degree of fidelity. Although they are active in that they can bind α -BTX, it remains to be determined whether the receptors synthesized in oocytes are functional molecules in terms of being able to form an acetylcholine-mediated ion channel in a membrane. Clearly, this system should be used to elucidate the mechanisms by which the receptor molecule is assembled and inserted into the membrane.

We thank Dr M. Dowdall for supplying fresh Torpedo and Dr A. J. Hale for research facilities.

TERS ARISING

The arrival of Equus

EVEN though papers which attempt to draw together a lot of diverse evidence are most important for the scientific community the authors of such papers should not neglect to acknowledge the basic analytical work on which they base their discussion. I feel that J. Brunet and I deserve to be quoted in discussion of the arrival of Equus in the Old World at least for Roccaneyra², probably the earliest European site to have yielded Equus, and probably the only one where Equus and Hipparion coexist. So far as I know, it was not V. J. Maglio³ but D. A. Hooijer⁴ and myself⁵ who, independently, stated that the first occurrence of Equus in the Omo beds was in member G of the Shungura Formation. Since 1973, we have often repeated that the arrival of Equus in Africa was about two million years ago⁴⁻⁹.

Lindsay et al.'s bibliography is quite instructive. Most of the papers cited on the first occurrence of Equus in Europe and Africa are themselves reviews, rather than original papers describing new material or stating new facts. People like J. Brunet, who has worked for years with equids, or D. A. Hooijer and myself, who have published about 30 papers dealing with equids, are ignored, although we were responsible for the basic descriptions and determinations.

I am sure that any specialist whose colourless original work has been neglected, involuntarily or not, in more appealing papers will understand why I decided, even so late, to write about such a trifle.

LINDSAY ET AL. REPLY—We regret that the important palaeontological contributions of Dr Eisenmann and others were slighted in our references. This was unintentional, but resulted from a bias towards selection of references with a chronological rather than a palaeontological message.

Certainly, the paper by Eisenmann and Brunet on the co-occurrence of Equus and Hipparion at Roccaneyra is an important palaeontological contribution for recognition of the appearance of Eauus in Europe. Our study was initiated with the expectation that the record of Equus at Montopoli would be demonstrably earlier than that at Roccaneyra, and we were more impressed with the proximity of their age assignment than with the palaeontological identity of the equids at Roccaneyra and Montopoli.

We cited Maglio² as an early review of East African biochronology in which faunal levels were characterized, including the Mesochoerus limnetus zone, with the appearance of Equus. Correlation of this faunal sequence had been questioned because of similar faunas with conflicting radiometric limits in the Shungura and Koobi Fora Formations—that conflict was resolved after further work on the radiometric dating, as discussed by Drake3. Our emphasis was on resolution of the conflict, and we concluded that the appearance of Equus in deposits of the Omo Basin, east of Lake Turkana, was contemporaneous with that at Olduvai Gorge. Unfortunately, we did not palaeontological the acknowledge contributions of Hooijer4, Eisenmann5, Churcher⁶, and others.

We think there might be a strong tendency for reviewers to cite other reviews, and similarly for analytical contributions to cite other analytical contributions. In spite of this, we recognize and appreciate the numerous palaeontological, radiometric, and stratigraphic studies of many researchers whose work we drew on for our review.

Pulsar birthrates

NARAYAN AND VIVEKANAND1 have obtained a minimum estimate for the birth rate of pulsars in the Galaxy of 1 pulsar per (100^{+100}_{-30}) f yr, where $f(=K^{-1}) \le 1$ is the beaming factor. They have obtained this estimate from the flow rate in period space, without recourse to the spin-down age $\tau := P/2\dot{P}$. At the same time, their estimated number of pulsars in the Galaxy is $N = 1.4 \times 10^{5\pm0.3}/f$, and they find that τ is a good measure of age for $\tau \leq$ 0.5×10^6 yr. Their method is elegant, but I find it hard to trust their result quantitatively, for the following reason.

Their birth rate N implies a mean pulsar age $N/\dot{N} \approx 4 \times 10^7$ yr which is some 10 times larger than the average age determined2 both from the fraction of young pulsars ($\tau < 10^6$ yr, for which τ is held to be a good measure of age) and from the kinematic ages z/\dot{z} , and also³ from the histogram of spin-down ages. It would imply that \(\tau \) underestimated the true age. However, according to our understanding of pulsars, τ measures their age for a dipole-coupling to their surroundings, and can only lose its property of an age indicator in the presence of some overtaking ageing mechanism (such as spin alignment4), in which case it would overestimate the true age.

If the birth rate derived by Narayan and Vivekanand can be trusted vaguely, it means that τ is not always as large an overestimate of age as suggested by kinematic ages. Such a trend does not surprise me in view of the two populations of pulsars which are expected if pulsars are born in binary systems⁵. A large fraction of all τ -old pulsars may be 'elder twins' born with a large τ_0 (>106yr, instead of $\leq 10^3$ yr), and for which τ is not a significant overestimate of age. At the same time, if pulsars are in general the younger twins, the birth rate of neutron stars should be approximately twice that

Another word of caution concerns the beaming factor whose value is often assumed to be 0.2. This estimate follows from the assumption of an almost circular beam cross-section, and independently from the fact that most supernova remnants lack a central pulsar. However, supernova remnants housing a pulsar would almost certainly have a filled-centre appearance, that is, be plerions, whereas shell-type remnants are expected⁵ to contain binary system neutron stars (like W50 around SS433). Moreover, pulsar beams may well have banana-shaped cross-sections, with $f \approx 1$. A beaming factor f near unity is likewise indicated by the high occurrence rate of interpulses $(\approx 5\%)$ if the latter come from the opposite magnetic pole.

With these modifications and ref. 2 in

mind. I arrive at a galactic neutron star birth rate of 1 in 20 ± 10 yr.

NARAYAN AND VIVEKANAND REPLY-It is known1 that the radio luminosities of pulsars decrease with age. Therefore, the observed sample of pulsars is biased towards the more luminous younger pulsars. Consequently, the average age of pulsars determined2 from the observed fraction of young pulsars $(\tau < 10^6 \text{ yr})$ underestimates the true mean pulsar age. The bias is probably even more stronger in the kinematic ages determined from z/\dot{z} because proper motions have been reliably obtained only for relatively luninous pulsars. On the other hand, in our analysis, we have accounted for radio luminosity selection effects and thereby obtained an approximation to the complete galactic population of pulsars. Consequently, our result $N/N \approx 11 \times 10^6$ yr is unbiased and a more reliable estimate of the mean pulsar age than the earlier approaches which typically gave 4×10^6 yr. Note, however, that age is not a very relevant parameter in our analysis, which is based entirely on pulsar flow in the P-P diagram (pulsar period to its time derivative). Moreover, the concept of mean pulsar age itself may not be very meaningful or useful if pulsars belong to more than one class with widely different active lifetimes.

Regarding the beaming factor K, we consider that the 5% occurrence of interpulses is consistent with a circular beam cross section and a value of K = 5 rather than with banana-shaped cross sections and K = 1.0

Solar-flare produced ³He in lunar samples

RAO AND VENKATESAN³ have reported a method for deducing the absolute solar cosmic ray (SCR) proton fluxes in the past few million years using SCR protoninduced ³He in the top surface layers of Moon rocks. To quote the authors: "even if there are minor diffusion losses, this method holds good as long as the losses are not depth dependent". I would like to point out that Moon rocks studied in this laboratory which are similar to those used by Rao and Venkatesan show severe 3He diffusion losses, up to 99% (refs 2-6), and the losses show strong depth dependence³⁻⁶. Another problem arises from the directly implanted solar flare ³He found in the top few millimetres of these Moon rocks³⁻⁶. This ³He component shows depth dependence and is about one order of magnitude higher in concentration than the SCR proton-induced ³He, therefore masking it in the top few millimetres of rock³. The rocks which we have studied, 68815 and 65315, excavated from south ray crater, have GCR and SCR exposure ages of 2 Myr, contain plagioclase as the major mineral and therefore are similar in many characteristics to the rocks studied by Rao and Venkatesan, 61016 and 64435. The near constancy of ³He/²¹Ne ratios which they suggest as an indication that depth dependence diffusion effects are not significant can also be misleading as the ²¹Ne diffusion pattern shows in our rocks a similar depth dependence to the 3He and

therefore the ³He/²¹Ne ratio might stay quite constant. We believe that Rao and Venkatesan were unable to observe the two effects, depth dependence diffusion and the directly solar flare-implanted ³He because first, only three layers of different depths were taken from each rock, and second, the layers were too thick (≥1.5 mm). We can judge from our fine sampling, nine for each rock in the range 0-15 mm and ~ 0.2 mm thick layers in the first 0-1 mm of range, that neither the diffusion pattern nor the SCR-implanted ³He would have been observed using the sampling technique of Rao and Venkatesan. I therefore consider ³He to be the wrong isotope for the use proposed unless the effects mentioned are taken into account.

RAO AND VENKATESAN REPLY-We point out that we discussed these issues in detail elsewhere1. Relevant points are briefly outlined below.

Our inferences regarding ³He losses are based on experimental results in rocks

61016 and 64435. The general agreement (within a factor of two) of exposure ages based on SCR-produced 21Ne and 38Ar and ³He, with the surface exposure ages based on particle tracks, could not have been observed if almost total loss of ³He had taken place by diffusion in these samples. Further, the diffusion effects of ³He and ²¹Ne are mass-dependent. Yaniv may not be observing such mass-dependent effects because 99% of the gas has been lost from his samples. The depthdependent diffusion will lead to variations in the ³He/²¹Ne and ³He/³⁸Ar ratios with depth, which is not borne out by the nearuniformity of these observed ratios in our samples. (Details are discussed in refs 1.

The peak temperatures to which some of these rocks were exposed on the lunar surface is ~370 K and the average temperature is 210 K; He loss can be partial but not almost total, at such temperatures, in these samples.

In some lunar plagioclases, 3He was lost and in some it was well retained. In a sensitive Gas ion-probe analysis of ⁴He in plagioclases, Müller et al. observed large amounts of ⁴He in two plagioclases (P4 and P2), with a capability of retention similar to that of ilmenite, whereas in some other plagioclases from soil 76501, no 4He was found. Shock effects also seem to be involved.

The occurrence and composition of directly implanted solar flare He and Ne in lunar samples is important. We are investigating the composition of solar flare Ne in these samples by selective chemical etching and subsequent stepwise thermal release methods. The long-term solar flare Ne composition seems to be similar to fractionated solar wind4. The long-term solar flare He composition is not well known, but the contemporary solar flare ³He/⁴He ratios (measured from spacecraft) vary from 1 to 0.01 and differs between flares5. Most of the 3He-rich flares are very weak and their contribution to the total He seems to be limited. It is not clear whether the long-term solar flare He composition is similar to the fractionated solar wind as in the case of Ne or varies drastically as observed in contemporary flare studies. Further controlled experiments are under way to understand these complexities.

Volume Holography and Volume Gratings

L. Solymar and D.J. Cooke

September/October 1981, x+468pp., £39.60 (UK only)/\$95.50, 0.12.654580.4

The book is devoted mainly to the study of the properties of volume holograms, such as efficiency, fidelity of reproduction and the generation of higher order modes, including also a chapter on the materials used for recording. The treatment is extended to volume gratings in general, in which diffraction effects at or near the Bragg angle are significant. Applications in the form of displays, optical elements and couplers, acousto-optic and electro-optic devices, computer memories and integrated optics are discussed.

Goat Production

edited by C. Gall

September/October 1981, xx+620pp., £41.40 (UK only)/\$99.50, 0.12.273980.9

The renewed interest in goats for both intensive production in temperate and extensive production in tropical countries has inspired this book. The 19 chapters are written by 18 leading authorities. On the basis of the widely scattered literature they discuss what is known in their fields drawing heavily on own research results, some of which are published here for the first time.

Stress and Fish

edited by A.D. Pickering

September/October 1981, xiv + 368pp., £24.60 (UK only)/\$59.50, 0.12.554550.9

This book extends knowledge by presenting original research in the context of a detailed review of the existing information. The endocrinological/physiological responses of fish to stress, fundamental to our understanding of the subsequent performance of fish, are given particular attention as are the problems of stress associated with intensive fish cultivation and the harmgul influences of man's activities on the aquatic environment.

Aquarium Systems

edited by A.D. Hawkins

September/October 1981, x+452pp., £27.80 (UK only)/\$67.00, 0.12.333380.6

This book was written as a practical guide to fish-keeping in the laboratory and is the result of collaboration between working scientists with first-hand experience in the subjects they have presented. It considers the basic aspects of aquarium design and construction, the supply of aquarium water and its treatment to make it suitable for the fish, the choice of materials for building the aquarium in order to minimize corrosion and contamination of the water, and other practical aspects of fish husbandry.

Mathematics in Biology

Series editors: Robin Sibson and Joel E. Cohen

This new series seeks to promote collaborative work among mathematicians, statisticians and biologists by providing a forum for the publication of important new work in this area on the boundary of two major disciplines. Both mathematical modelling and the analysis of biological data will be covered, especially in relation to areas of currently active interest in biology.

Mathematics in Biology Series

Circular Statistics in Biology

Edward Batschelet[†]

August/September 1981, xvi+372pp., £28.80 (UK only)/\$69.50, 0.12.081050.6

There have been considerable advances in the study of circular statistics in the last twenty years. Circular Statistics in Biology seeks to provide a comprehensible guide to this field for the biologist and scientist who have a large amount of circular data to deal with but a limited knowledge of mathematical and statistical theory. The emphasis is on interpretation and analysis rather than unnecessary theory and many illustrative examples are provided.

BOOK REVIEWS

Chinese puzzles

John Maddox

THE time has gone when people could bring conversation in the West to a halt by saying that they were just back from China. Indeed, the conversational gambit is dangerous, for there is as likely as not to be somebody in the gathering who can boast of having found a better hotel, or of having been allowed to visit Chinese Mongolia or Tibet. Yet China remains a puzzle, not only because mutual travelling is still only a trickle but because of language and the sheer strangeness of China as seen from the West and, no doubt, vice versa.

Science in Contemporary China is, in the circumstances, a welcome book even though its defects, sometimes serious and often irritating, also command attention. The book is a compilation of travellers' tales from the late 1970s brought back from China by 26 scholars of various disciplines, many of whom seem to have made two or three journeys under the auspices of the Committee on Scholarly Communication with the People's Republic of China, itself an offshoot of the National Academy of Sciences in Washington but funded, for this purpose, by the National Science Foundation. But since most of the contributions are well laced with handlists of laboratories, and the names of their directors, the book is likely to be most used as a kind of Baedeker — a guide by which intending travellers from the West can plan their journeys. That is not something to be scorned.

The most glaring flaw is that the book. according to its editors and Professor Walter Rosenblith, the chairman of the supervisory committee, is uneven. In many ways, that is an understatement. Some contributions are merely handlists. Others sensitively relate the condition of some discipline now (or in 1978 or 1979) with the great events of the Cultural Revolution which then seems more than ever a calculated madness. A more forgivable defect of the book is that most of the journeys on which it is based were made in that dreadful period when the Cultural Revolution had come to an end but when Mao Zedong (according to the pin-yin transliteration) was still nominally in the saddle. Some travellers were plainly mystified by what was happening around them, at least until the changing scene was crystallized and made familiar by the great National Science Conference in Peking (sorry, Beijing) in March 1968.

Travellers to foreign lands must be wary of the three most obvious traps — those of generalizing from impressions, of writing patronizingly and of writing with stars in their eyes. This bunch of travellers has been

Science in Contemporary China. Edited by Leo A. Orleans with the assistance of Caroline Davidson. Pp.599. ISBN 0-8047-1078-3. (Stanford University Press: 1981.) \$35.

reasonably circumspect. Now and again, first impressions enliven the separate catalogues of information — Leo Goldberg was obviously shocked to learn of the ups and downs of the Purple Mountain Observatory (Nanjing) from which the astronomers were driven after the Japanese occupation in 1937. The general first impression that Chinese researchers use less sophisticated equipment than their colleagues in the West has, however, been carefully confirmed; and there is a thorough account of what is being done by the Chinese Academy of Science to put things right.

For the most part, devotional prose has also been avoided. Fang Yi, the vice-premier with responsibility for science and technology in 1968, made a great impression on several of the travellers as did Deng Xiaoping (deputy premier at the same time) on the smaller number who had the luck to meet him. Some seem to have regarded the national plan announced in March 1978 as having the force of Mosaic tablets, but collectively the travellers have given a good account of how the plan is having to be matched against economic and social reality.

Now and again, the travellers have fallen into the trap of patronizing those whom they observed. The impression is heightened by the way in which China is so often called the PRC. One writer asks how it can be that the Chinese choose to lavish surgical skill on intricate operations when they have so few Western-style doctors per 10,000 population. Even, in an extended footnote, Joseph Needham (the author of the monumental Science and Civilization in China) is patronized because his book is not "philologically sound". But these are minor points.

For the rest, this Baedeker, based though it is on 26 snapshots of China, is full of absorbing information. Not merely can one learn that C.N. Yang (the field theoretician) is the son of K.C. Yang, who took a PhD in mathematics in Chicago in the 1920s, but that Chen Jingrun was the first to prove (in 1966) that, above a certain size, every even number can be written as the sum of a prime number and another which is either itself prime or the product of two prime numbers; that China is heavily committed to superconducting technology for reasons not readily understood; that

the commitment to high-energy physics derives from Mao's interest in the philosophical implications (but that the 50 GeV accelerator will not now be finished until 1985); that there is a project to synthesize a transfer-RNA molecule and it appears to be customary, when an active compound has been isolated from some traditional medicinal herb, to synthesize the pure chemical so as to avoid the associated side-effects. China's need of military electronic equipment is urgent. Computers still languish.

Collectively, the snapshot is clear. But what is happening to the people? The Cultural Revolution lasted for 15 years, almost a generation, and university posts were either not filled or filled with the wrong people. Science in Contemporary China records in several places that Chinese hosts were aware of the problems foolishly created, and that they were doing their best to put things right. How quickly, one must wonder, will they succeed?

Anecdotally, this book provides some evidence of change in the right direction. I was pleased to find in it the name (almost unrecognizable behind the pin-yin) of a graduate student at Manchester many years ago. He was so homesick that he travelled every other week to Liverpool for a decent meal in St George's Square. In 1953, he caught Mao's student boat back to China. We were surprised to learn that as an F-centre expert he planned to help with the "building of a dam"; only afterwards did we understand that it was a project to do with weapons. But when seen at the height of the Cultural Revolution, he was working as a kind of filing clerk at the Academy. Now, it seems, he has been rehabilitated, the head of a division of an institute in Beijing.

Only occasionally do the contributors have the time to reflect on what they describe, but Saunders Mac Lane (who writes about mathematics) does best. He gives an account of how his delegation chose to argue with their Chinese hosts about the virtues of mathematics - is it elegance ("beauty") or utility that matters most? The encounter was apparently rowdy, and the question unresolved. The reason seems to have been a difference of idiom - which is not merely a name for a pretty turn of words. What remains to be learned, from the West, about China is whether present puzzles will melt away with the passage of time or whether, on the other hand, the idiomatic gulf will prove to be unbridgeable.

John Maddox is Editor of Nature.

Physics for philosophers and philosophy for physicists

D. ter Haar

Superposition and Interaction: Coherence in Physics. By Richard Schlegel. Pp.302. ISBN 0-226-73841-8. (Chicago University Press: 1981.) \$22.50, £13.50.

This is an interesting book but - to my mind — very much a curate's egg. The first question which comes to mind is: for whom is the book meant? The author himself states that although at times he had thought of philosophers as his audience, his primary prospective audience is among physicists or other physics-minded scientists "who have some technical knowledge of special relativity theory and of quantum theory - as given, say, in introductory courses in those topics in American universities". The next question is: what is the message which the author wants to convey? The answer is that he wishes to suggest that there is a fundamental coherence in physics which can be shown especially to exist when we consider the two main pillars of what is still called "modern" physics, namely, the special theory of relativity (now 76 years old) and non-relativistic quantum theory (in its late sixties). The suggestion is that in both of these theories superposition (that is, the fact that if one has two separate solutions of the equations, a line or combination of them is also a solution) plays an essential part and interactions with an observer are a deciding factor. This is orthodoxy as far as quantum theory is concerned, but takes some swallowing when we come to special relativity. However, while this book does not give any compelling reasons - in my view, not even aesthetic reasons - to accept this thesis, there do not seem to be any experimental data which contradict it. This is, perhaps, not surprising, as no experimenta crucis are suggested to decide for or against the author's views.

Let me first of all list those aspects of the book which I found most admirable and from which I benefited most. For a careful and well-informed reader it contains much that is illuminating. In particular, I found the first and last chapters of great interest. The discussion in the first chapter of the contents of classical physics - going back to Aristotle - and of the importance of models in theoretical physics in general and in classical physics in particular is excellent. The last chapter containing a "summertime conversation" between two physicists, the wife of one of them and a philosopher gives a cogent and on the whole clear account of most of the important points made in the main body of the book.

The second volume in the series Genetic Engineering (for a review of Vol.1 see Nature 292, 480) has recently appeared. Genetic Engineering 2 contains four contributions on gene evolution, genomic libraries, restriction enzymes and gene cloning in yeast. Prices are: £9.80, \$24.

One might object to quantum mechanics as a deus ex machina and the relegation of God to a superior watchmaker — miracles seemed to have no place in the Universe inhabited by these four people — but these are minor objections. Another excellent discussion is the one of the clock paradox, where the author follows a suggestion made to him by Einstein himself and uses three uniformly moving inertial systems to resolve this paradox.

I now come to a number of points where I feel the author has seriously diminished the usefulness of this mainly philosophical treatise, especially for younger physicists. I would hesitate to give the book to my own pupils without a number of caveats, since in a number of places the theory given is wrong (or at least so poorly formulated as to be seriously misleading). In the account of measurement in quantum theory there is, in my opinion, insufficient emphasis on the difference between the preparation for a measurement and the measurement itself. However, the most fundamental error and one which crops up several times — is in the discussion of pure states and mixtures. A mixed state cannot be represented by a wavefunction, but needs a density matrix. The concept of a density matrix - so central in the theory of measurement - is, in fact, nowhere mentioned in this book.

Other points where the text is, to say the least, misleading are where the author states that the Maxwell equations are linear (homogeneous) differential equations for which the superposition principle holds, without stating that this is only true for the Maxwell equations in vacuo. It is also confusing to stress de Broglie's introduction of the relations between energy/momentum

and frequency/wavevector as against Schrödinger's introduction of the wave equation in order to find a close relation between special relativity and non-relativistic quantum theory. After all, we still do not have a complete relativistic wave equation, but only approximate equations such as the Dirac and Klein-Gordon equations which are valid in the not-very-relativistic domain.

In a book which is mainly philosophical in tone, one would expect careful use of language and it is disappointing to find a number of sloppy expressions. It is probably too much to expect that a careful distinction is made between utilize ("to make useful, turn to account" according to the OED) and use, but a vital point is missed when it is stated that "the Greek word atomos means 'individual'." As an important issue in the book is the distinction between macroscopic and microscopic systems, somewhere a careful definition of those terms should be given and the dividing line drawn between them - or it should be stated that it is often impossible to draw such a line. The general problem of what are physically meaningful questions and which are mainly philosophical ones, although hinted at several times, could also have been considered more carefully. For instance, I feel strongly that in a book of this kind there should be a clear discussion of the fact that a wavefunction only has a meaning in as far as it can predict the outcome of an experiment - this, after all, makes quantum theory a theory which can be falsified.

D. ter Haar is a Fellow of Magdalen College and Reader in Theoretical Physics at the University of Oxford.

What price the diversity of species?

A.D. Bradshaw

Conservation and Evolution. By O.H. Frankel and Michael E. Soulé. Pp.327. ISBN hbk 0-521-23275-9; ISBN pbk 0-521-29889-X. (Cambridge University Press: 1981.) Hbk £25, \$49.50; pbk £7.95, \$17.95.

THE natural ecosystems of the world are disappearing at a frightening speed. Tropical rain forests are being destroyed at a rate of 4.7 ha min⁻¹ and will be gone within 50 years. Every year sees a further 6 million hectares of arable land. Although some areas will be almost impossible to cultivate, the ingenuity of people pressed for space must not be underestimated; and even if cultivation is not possible, hunting, logging and grazing will inevitably increase drastically beyond their present high levels.

Against this scenario, what will be left of

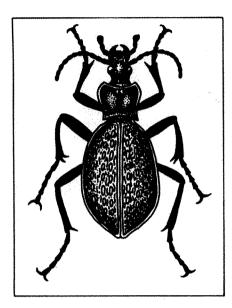

the wealth of plants and animals on this planet? Some species, r selected, of small size and with tolerance of man-made environments, will certainly survive. There are plenty of species left in England and China. But the great diversity will inevitably be reduced. This book is a critical analysis of what is likely to happen, written by two well-known population geneticists, highly experienced between them in both wild and cultivated species.

If species are to be conserved at all, the authors argue that they must be conserved without loss of genetic variability. For outbreeding organisms, from considerations of the effects of inbreeding/mutation/selection equilibria the authors conclude that a minimum effective population size of 50 is necessary.

Springer Series in Experimental Entomology

Editor: T. A. Miller

T.A.Miller

Insect Neurophysiological Techniques

1979. 148 figures, 4 tables. XII, 308 pages. Cloth DM 56,80; approx. US \$ 25.90 ISBN 3-540-90407-7

Neuroanatomical Techniques

Insect Nervous System

Editors: N.J.Strausfeld, T.A.Miller With contributions by numerous experts 1980. 172 figures (26 figures in color). XVI, 496 pages Cloth DM 98,—; approx. US \$ 44.50 ISBN 3-540-90392-5

Cuticle Techniques in **Arthropods**

Editor: T.A.Miller With contributions by numerous experts 1980. 112 figures. XIV, 410 pages Cloth DM 114,-; approx. US \$ 51.90 ISBN 3-540-90475-1

This volume gives a comprehensive overview of the methodology used in the study of the physical, chemical and biochemical properties of the arthropod cuticle. Containing a wealth of information and critical evaluations not available in any other single source, it also covers cuticle culturing, preparation for electron microscopy, and measurement of water transpiration and insecticide penetration. The material includes sufficient documentation to allow exact repetition of experiments, an important feature not always afforded by journal accounts.

Neurohormonal Techniques in Insects

Editor: T.A. Miller With a Foreword by G.S. Fraenkel With contributions by numerous experts 1980. 90 figures, 23 tables. XXIV, 282 pages Cloth DM 79,—; approx. US \$33.90 ISBN 3-540-90451-4

This book discusses the broad range of current neurochemical research on neurohormones. Although insects are used as models, the information offered is applicable to a variety of animal systems.

Thorough desciptions of the methods of bioassay, extraction, and identification of peptide hormones synthesized and released from nerve cells are given.

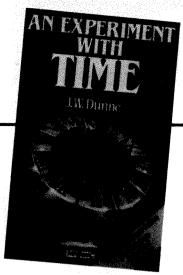

Neurohormonal Techniques in Insects provides essential technical information for researchers in insect neurochemistry, biochemistry, and neurobiology.

Sampling Methods in Soybean Entomology

Editors: M.Kogan, D.C.Herzog 1980. 252 figures, 65 tables. XXIII, 587 pages Cloth DM 88,-; approx. US \$40.00 ISBN 3-540-90446-8

This book summarizes the fundamental, experimental, and analytical procedures which are indispensable for studying demographic data on insect populations. Practical procedures for obtaining relative and absolute data on arthropod parasites, predators, and diseases are examined in-depth. Construction of various sampling devices is explained, as well as selection of the most appropriate collecting techniques based on the particular characteristics of the species, cost of collection, and accuracy of collected data. Development of operational standards for running these tests is stressed.

British Journal of CLINICAL PHARMACOLOGY

ESSENTIAL INFORMATION AT YOUR FINGERTIPS. EVERY MONTH!

Published monthly on behalf of the British Pharmacological Society, *British Journal of Clinical Pharmacology* is as fast-moving as the area of science it examines:

Bridging the gap between medical professions, clinical research and the pharmaceutical industry.

Contáining papers and reports on all aspects of drug action in man, in both health and disease.

Providing free copies of the proceedings of selected symposia on new methods, new drugs and new approaches to treatment, to all subscribers.

To keep up-to-date in this fast-moving area of science why not join the ever-increasing number of clinical pharmacologists all over the world who rely on the *British Journal of Clinical Pharmacology* as their professional journal.

ANNUAL SUBSCRIPTIONS

Orders should be accompanied by remittance, cheques made payable to Macmillan Journals Ltd: Subscription Department, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

Sample copies are also available from the same address.

But if conservation is to include the possibility of continuing evolution then the minimum population size is 500. Once this conclusion is reached the problems of conservation become apparent. The minimum territory of a pair of mountain lions is 52 km²; to conserve this species requires an area about twice the size of Yellowstone National Park. There are therefore few reserves in the world that are large enough to ensure the survival of the dominant carnivores, and there is no doubt the majority are doomed to disappear.

Yet nature reserves present the only possible solution. In which case there are criteria of population genetics and biology which must be observed if reserves are to be designed to function properly. Size is crucial according to island biogeographical theory, but so is migration. As a result there are arguments that small reserves are possible if there are connecting corridors. But the authors point out that this will only work in a limited number of cases.

Even the r selected species, notably our crop plants and their wild relatives, have problems. It is crucial that we maintain genetic diversity to satisfy our present and future needs for food production. This means genes to cope with specific individual problems such as day length or disease, and genes by which we can build up co-adapted complexes for characters such as yield. The authors show that these genes are scattered in wild and cultivated material, often in places that cannot be predicted.

For conservation and continued evolution, a diversity of populations must be maintained, if possible in natural conditions. So far, because of geographical expansion from migration and trade, the diversity in these species has actually increased. But now the success of modern agriculture and plant breeding has sent the process into reverse, and whole groups of cultivars, such as the Welsh upland wheats and barleys, have completely disappeared. The solutions endorsed by the authors are various: in situ and ex situ dynamic conservation, and static conservation by storage, of which seed storage is perhaps the most efficient. But they do not offer any easy solutions to the problem of what to store, except to emphasize the need for international co-operation.

This book is a remarkable survey of a problem which is crucial to us all. Not only does it list over 600 references but it achieves a remarkable synthesis and perspective, based on a masterly understanding of theory as well as practice. It is enormously readable because of its simple and enthusiastic style. It is critical reading for plant and animal breeders, and all ecologists, so that they can better argue with politicians about what has to be done, before it is too late.

Liquid crystal measurement

J. W. Emsley

Physical Properties of Liquid Crystalline Materials. By W.H. De Jeu. Pp.133. ISBN 0-677-04040-7. (Gordon and Breach: 1980.) \$35.25.

EVERY schoolboy knows that there are liquid crystal display devices, but a relatively few graduates are familiar with this "fourth state of matter". There is certainly a need for introductory texts on the physical properties of these materials. to supplement George Gray's excellent Molecular Structure and the book, Properties of Liquid Crystals (Academic, 1962), which covers their general properties. This short book by De Jeu is the first of what promises to be a series, edited by Professor Gray, on liquid crystals. It has, however, a misleading title since it does not cover all physical properties and is confined to discussing only the simplest mesophase, the nematic. This does have the advantage of making it a book that will be read rather than one too complex and long to appeal to those interested in other aspects of liquid crystals.

Five physical properties are discussed: magnetic susceptibility, refractive index, dielectric permittivity, elastic constants and viscosity coefficients. Each topic is introduced by a discussion of the basic physics, which makes heavy demands on the background knowledge of the reader.

There follows a survey of methods of measurement and a discussion of the work which has been done. The author draws heavily on his own research and does not attempt a general review, but this again adds to the readability of the book and conveys a sense that much remains to be done.

Physicists, chemists and engineers interested in liquid crystallinity will welcome this book as providing a short, readable account of the five physical properties. It is written primarily with experimentalists in mind and it has a particularly useful chapter on sample preparation. It is less successful at explaining the significance of the results. mainly because of a deliberate decision not to get involved with the details of the various theoretical models developed in recent years. Restricting the scope of the book to those topics in which the author has been directly involved was a wise decision, for although one might wish for more discussion of cholesteric or smeetic phases, or a more critical review of theory, what is included is discussed with an authority derived from a long experience in the laboratory.

J. W. Emsley is a Senior Lecturer in the Department of Chemistry at the University of Southampton.

Consolidating fungal biochemistry

P.G. Mantle

Lipid Biochemistry of Fungi and Other Organisms. By J. D. Weete with contributions by D.J. Weber. Pp.388. ISBN 0-306-40570-9. (Plenum: 1981.) \$45, £28.35.

THIS volume is a reincarnation of the authors' previous book, Fungal Lipid Biochemistry, published by Plenum in 1974. The text has been completely rewritten and revised but still centres on the distribution and biochemistry of fungal lipids — fatty acids, acylglycerols, sterols, phospholipids, aliphatic hydrocarbons and sphingolipids. New aspects covered in the present volume include a brief history of fungal lipid research, more comprehensive treatments of lipid taxonomy and substrate conversion into stored lipid, a description of the multifunctional yeast enzyme for fatty acid synthesis, the biosynthesis of polyprenols and carotenoids, and a review of the role of fungal lipids in sporulation and spore germination. The bibliography has been correspondingly increased and, where appropriate, reference is made to contrasting bacterial, plant and animal systems.

A few minor typographical errors can be

recognized and I was somewhat surprised to find myself credited (Table 3.7) with research in the field of phycomycete fatty acids. Nevertheless, the authors should be congratulated on condensing the essence of about 1,000 research papers into a lucid text supplemented liberally by comprehensive tables and figures.

It is often only when someone gives the time and care to review a subject that the gaps in our knowledge of an otherwise diffuse topic become well defined. Fungal lipid metabolism is a case in point. Thirty years ago this book would have been simply a pamphlet listing some of the oils contained in fungi. Biochemistry has since moved so fast that the lipid composition of representatives of the major groups of fungi is now fairly well documented and the biosynthetic routes are generally understood. It is, however, notable that although regulatory mechanisms for fatty acid synthesis have been well researched, the regulatory interactions involving lipids in whole-organism metabolism are largely unknown. This is perhaps not surprising since it is bound to be very complex. Nevertheless, it is such areas of knowledge which

A.D. Bradshaw is Professor of Botany at the University of Liverpool.

will be invaluable in fully understanding fungi as organisms. This is particularly relevant to species which interact parasitically with other organisms or which have the ability to produce complex secondary metabolites, whether suitable for exploitation as pharmaceuticals or agrochemicals or whether hazardous on account of their propensity to act as mycotoxins. Often these functions are closely associated with lipid metabolism, frequently yielding metabolites from a common pool of key intermediates.

In an age when biochemistry is concentrating so much on the molecular level, however exciting, it would appear that metabolic biochemistry is being neglected. This book will be valuable in focusing attention on fungal biochemistry — students, teachers and researchers in the field of microbial biochemistry will do well to consult it.

P.G. Mantle is a Senior Lecturer in the Department of Biochemistry, Imperial College, University of London.

Academic synergism

J.B. Butterworth

Universities in Partnership. By I.C.M. Maxwell. Pp.480. ISBN 0-7073-0270-6. (Scottish Academic Press: 1980.) £15.

Universities in Partnership describes the first 25 years of the work of the Inter-University Council for Higher Education Overseas, from the time when it was set up by the British universities in 1946 to assist in the creation of new universities in colonial territories which were rapidly becoming independent. Gradually the IUC was called upon to fulfil a wider role in helping these new institutions to develop their academic potential and train their staff. More recently, it became an important vehicle in facilitating better two-way communication between the universities in the UK and some 35 others in developing countries, an important partnership, based in equality, giving benefits to both sides by a number of different forms of relationship of which links between departments have become particularly important.

This record of the universities with which the IUC has had association is impressively comprehensive and portrays their development as seen from the standpoint of the IUC. One is grateful to the author, Mr Maxwell, for his immense work of distilling the records of the IUC and, from a voluminous amount of material, producing such a readable and full account. At a time when the IUC is becoming the IUPC and merging with the British Council, it is important that all of this material should be available within the covers of one volume.

The book is divided into three parts, the first of which is particularly interesting in

that it gives a short and attractive account of the basic theories upon which the work of the IUC has been based, and of the way in which those theories or principles have changed with time. In Part 2, "The Foundation and Growth of the Universities", Mr Maxwell presents the universities in considerable detail, much of which comes from the archives of the IUC. The book seems to change gear between Part 1 and Part 2, the earlier section dealing in a lively way with the principles and policies which evolved over the 25 years. The second part, no doubt because it is dealing with each individual university and is condensed from the IUC records, does not always say what one might wish to hear. In the development of any institution people are crucial, and the end of the period covered by Mr Maxwell was particularly important because indigenous Vice-Chancellors were taking over from expatriates; one would have liked to know more about those individuals whose influence had been crucial in the development of particular universities.

The book, of course, is intended to be a history of the IUC and not of the individual universities with which it was associated. But too close an adherence to the reports of commissions and the decisions of Senates and Councils may not always reveal the reality which is the university. Moreover, it would have been interesting if Part 2 or Part 3 on the role of the IUC had explored more fully some of the important themes referred to earlier in the book, especially the historical growth of the concept of a developmental university. The ideas and plans already current in the 1960s, as the Kericho Conference in 1966 bears evidence, were having and were to have considerable effect upon the new universities in developing countries. A prime example is the concept of an umbrella university such as Malawi, taking within iteself virtually all post-school education. Another is the single university catering for a number of different countries, evolving from the University of the West Indies, to the University of Botswana, Lesotho and Swaziland, and the experience there acquired being applied in the University of the South Pacific. The concept of a developmental university advanced rapidly after 1970 and it might have been advantageous if Mr Maxwell had not stopped abruptly at that date, for a deeper exploration of these themes could have given guidance and illumination to university development both now and in the future.

Nonetheless, we should be grateful to the author for the valuable work of reference he has made available to us. Those who consult it about particular events in the history of any of the universities are unlikely to be disappointed; it is an extensive and objective record.

J.B. Butterworth is Vice-Chancellor of the University of Warwick, was Chairman of the IUC from 1968 to 1977, and becomes Chairman of the IUPC from 1981.

Of bugs and brains

Howard C. Berg

Bacterial Chemotaxis As a Model Behavioral System. By Daniel E. Koshland. Pp. 193. ISBN 0-89004-468-6. (Raven: 1981.) \$19.50.

BACTERIA, the most primitive free-living organisms, continuously monitor the concentrations of chemicals in their environment, decide whether these concentrations are rising or falling, shift gears in their rotary engines and swim toward regions that they find more favourable. The modern armament of genetics, biochemistry and biophysics has been brought to bear on this remarkable behavioural system, and some of the processes involved are now understood in molecular detail. Professor Koshland surveys this work in terms intended for both the educated layman and the specialist, striving, as he puts it, to bridge the gap between general interest and scientific accuracy. He then moves with some temerity to a discussion of the function and malfunction of the human brain, arguing that the biochemistry of bacterial chemotaxis is relevant to the nervous system of human beings themselves.

This is a provocative book. It speaks with authority about the interactions of ligands with receptors, receptors with signallers, and signallers with enzymes that methylate and demethylate. It describes models for signalling and adaptation that, although incomplete, have led to a number of fruitful biochemical studies. It contains lively speculations on necessity and chance, memory and learning, and even love and hate.

But I have serious reservations. This is a personal account. The book does not adequately treat pioneering work on bacterial motility and chemotaxis done outside Berkeley. Nor does it make any attempt to place in proper historical perspective the idea that the nervous system of higher organisms evolved from reactions that can be found in the most primitive living things, or the hope that a knowledge of the mechanisms of bacterial chemotaxis might contribute to our understanding of neurobiology and psychology. These concepts are not new. Neurobiologists already know that they need to learn more about the biochemistry of the brain. A biochemist of Professor Koshland's experience might have been expected to offer more insights into problems that they might profitably pursue.

I prefer to think of bacteria as objects of fascination in their own right. Indeed they may prove to be more sophisticated than cells of the human brain. Bacteria have been around for billions of years, and individuals in each generation have had so survive on their own merits.

Howard C. Berg is Professor of Biology at the California Institute of Technology, Pasadena.

Professor D N Wade, Department of Clinical Pharmacology, University of New South Wales, PO Box 1 Kensington, NSW, Australia Aims and Scope

Toxicology is the study of the reactions, both adverse and compensatory, of living creatures to noxious materials. The hazards to which man is exposed and the manner in which he reacts to them from the moment of conception and thereafter throughout life is the subject of Human Toxicology. This new journal embraces both animal research, where it has a direct significance for man, and studies on man himself. These studies may be biochemical, physiological, pathological, clinical and epidemiological but will all be designed to increase our understanding of the action of noxious substances in the body and of means to counter their effects. All papers will be subject to peer review.

Main Features

The following material will appear on a regular basis:

- * Original papers of a high scientific standard on all aspects of human toxicology, embracing both animal research and studies with humans
- * Short communications
- * Invited comment on current matters of professional interest
- * Editorials on topical issues
- Review papers
- * Book reviews

Call for Papers

The submission of suitable papers for editorial consideration is welcomed. Papers must be in English and two copies should be submitted. References, collected at the end of the paper, should include the author's name, year of publication, title of article, title of publication, volume number and first and last page numbers. They should be listed in alphabetical order. A detailed list of *Instructions to Authors* can be obtained from the Publisher. Papers should be sent directly to the Editorial Secretary, Human Toxicology, 4 Little Essex Street, London WC2R 3LF England, or to Human Toxicology, Nature, Suite 1503, 15 East 26th Street, New York, NY 10010, USA.

CANCELLATIONS MUST BE RECEIVED NO LATER THAN 5 p.m. ON THURSDAYS PRIOR TO ISSUE DATE.

SENIOR Scientific Officer with good practical experience in HLA typing required to take technical charge of busy routine laboratory associated with a large Bone Marrow Donor Register. Work necessitates close collaboration with hospitals engaged in bone marrow transplantation and with departmental research projects. Ability to maintain high laboratory technical standards essential. Salary scale £5,500 to £7,110 plus London Weighting. Please write in first instance with CV to D C O James, Anthony Nolan Laboratories, St Mary Abbots Hospital, Marloes Road, London W8. (Tel: 01-937 2660). (9392)A

POSTDOCTORAL Research Associate. Position available as soon as fall, 1981, for PhD in cell biology, biochemistry or molecular biology, to join program on UV transformation of human skin cells, DNA damage and repair in these cells, and in skin in vivo. Experience in cell culture and/or biochemistry of mammalian cells desirable. Appointment initially for one year renewable. Apply to: Dr Betsy M Sutherland, Biology Department, Brookhaven National Laboratory, Associated Universities, Inc., Upton, LI, New York 11973. An equal opportunity employer m/f. (NW834)A

nature

seeks a

WASHINGTON CORRESPONDENT

to succeed David Dickson, who will be leaving his post in Washington on 31 March 1982. The post is central to *Nature's* reporting of developments affecting science in North America and elsewhere.

Applicants should be English-speaking, preferably with some first-hand knowledge of the United States and should also have

- * a university degree (preferably in science)
- * at least two years' experience of written journalism (preferably with a weekly or daily periodical, but not necessarily scientific)
- * a broad interest in current affairs.

The successful applicant will be employed by Nature America Inc., initially for a fixed term (to be negotiated). To allow for a spell in the London office of *Nature* and a period of overlap in Washington, applicants should be able to be free no later than 1 March 1982.

Salary, travel allowances and other conditions of employment by negotiation.

Applications, including a full curriculum vitae, should be plainly marked "Job application" and addressed to the Editor, Nature, Macmillan Journals, 4 Little Essex St, London WC2R 3LF or Nature, 15 East 26 St, New York, NY 10010, to arrive before 30 September 1981. (9324)A

UNIVERSITY OF BRISTOL DEPARTMENT OF BACTERIOLOGY POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for this post, which is available immediately, to work on mechanisms that inhibit the transposition of transposable elements, particularly those encoding drug-resistance. Experience in recombinant DNA technology is desirable. The appointment will be for three years.

Starting salary will be in range 1A of the scales for Research and Analagous Staff (£6,070 — £6,880 pa).

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent, as soon as possible, to Dr P M Bennett, University of Bristol, Department of Bacteriology, The Medical School, University Walk, Bristol BS8 ITD. (9408)A

UNIVERSITY OF OTAGO Dunedin, New Zealand LECTURER (Part-time) IN FOOD CHEMISTRY

Applications are invited for a lecturership (part-time) in Food Chemistry in the Department of Human Nutrition of the Faculty of Home Science.

The appointee will contribute to the Food Science sections of Departmental teaching. The post is suitable for a Food Scientist to combine with Consulting or R and D work, or it could be combined with postgraduate study. Up to a half-time position is available.

Salary: Lecturer — Pro Rata NZ\$19,140 — \$23,520 per annum.

Further detailed information is available from Professor J A Birkbeck, University of Otago, Department of Human Nutrition, Dunedin, New Zealand. A Statement of General Information and conditions of appointment including method of application is available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WCIH OPF, or from the Registrar of the University, PO Box 56, Dunedin, New Zealand.

Applications close on 30 September 1981. (9422)A

UNIVERSITY OF EDINBURGH DEPARTMENT OF BOTANY POSTDOCTORAL RESEARCH FELLOW

Applications are invited for this SERC funded post tenable for three years from November 1981 to work on the taxonomy of perennial bromegrasses under the supervision of Dr P M Smith. The work will include anatomical and morphological investigations and the applicants should have a good Honours degree in Botany and have a PhD or similar experience in plant taxonomy.

Applications, together with the names of three referees, should be sent by 30th September 1981 to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL. Please quote Reference 5050. (9427)A

in the
DEPARTMENT OF

PHYSIOLOGY & PHARMACOLOGY

The University of Queensland invites applications for a Chair of Physiology in the Department of Physiology and Pharmacology which became vacant in January, 1981, with the resignation of Professor G D Thorburn. Applicants should be able to present evidence of substantia research achievement and acknow ledged leadership in the field o Physiology. The successful applican will be expected to demonstrate an foster excellence in research, and wi be responsible to the Head of th Department of undergraduate an postgraduate teaching in keepir with Faculty Board and Depar mental requirements.

Salary: \$A41,509 per annum. To position is subject to the availabil of funds.

Additional information a application forms are obtains from the Association of Comm wealth Universities (Appts), Gordon Square, London WC OPF, (9404).

FRESHWATER BIOLOGICAL ASSOCIATION BIOMETRICIAN/ STATISTICIAN

required for Windermere Laboratory to initiate research in biometry as applied to pupulation dynamics of benthos, plankton and fish, sampling freshwater organisms and chemical/physical variables and experimental studies in collaboration with biologists and chemists. Minimum of 2.1 honours degree in statistics/biometry/mathematics or science degree plus statistical training or experience. Conditions analogous to HSO/SSO in Civil Service, starting salary between £6,075 and £7,644 pa.

Full details: Secretary, FBA, The Ferry House, Ambleside, Cumbria LA22 0LP (096 62 2468). Closes 7 Sept. (9314)A

KING'S COLLEGE LONDON RESEARCH TECHNICIAN GRADE 3

Applications are invited from persons interested in working on the control of globin gene expression in the frog. Xenopus laevis, in our Biophysics Department at Drury Lane WC2. Experience of work with nucleic acids, enzymes and bacteria would be an advantage. The successful applicant will also help with the administrative running of the laboratory and with the preparation of undergraduate practical classes. Salary on a scale rising from £5,688 pa (incl) to £6,489 pa (incl). 37½ hour week, Monday to Friday. Five weeks' annual holiday. Annual season ticket loan. Superannuation Scheme.

Apply in writing as soon as possible with a curriculum vitae and the names and addresses of two referees, to The Head Clerk (Ref: N226996), King's College London, Strand, London WC2R 2LS. (9415)A

... UNIVERSITY OF NEWCASTLE UPON TYNE DEPARTMENT OF BIOCHEMISTRY TEMPORARY RESEARCH ASSOCIATE

Applications are invited for an MRC-funded position of temporary Research Associate in the above department. The post is tenable for three years from 1st October, 1981 or as soon as possible thereafter.

The project will investigate the regulation of the activity of branched-chain 2-oxo acid dehydrogenase by phosphorylation — dephosphorylation. Experience of enzyme purification and/or protein phosphorylation would be beneficial.

Initial salary will be at the rate of £6,070 per annum within the range £6,070 — £6,475 — £6,880 on the Range 1A scale.

Applications, including full curriculum vitae and the names and addresses of three persons to whom reference may be made, should be sent, as soon as possible, to Dr S J Yeaman, Department of Biochemistry, Ridley Building, University of Newcastle upon Tyne NE1 7RU, from whom further details may be obtained. (9402)A

UNIVERSITY OF NATAL DEPARTMENT OF BOTANY PIETERMARITZBURG

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin, for appointment to the post of:

SENIOR LECTURER

Minimum qualifications would be a PhD in Botany or closely allied field and/or suitable academic or research experience.

The successful incumbent will be responsible for the organisation and teaching of courses in the fields of Plant Taxonomy, Plant Biosystematics and Population Biology of Plants.

Major areas of research within the Department include Angiosperm Taxonomy, Experimental Morphology, Phycology, Plant Physiology and Terrestrial and Aquatic Ecology.

The salary will be in the range of: R14,370 — R20,850.

The commencing salary will be dependent on the qualifications and/or experience of the successful applicant. In addition, an annual service bonus equivalent to 93% of one month's salary is payable, subject to Treasury regulations.

Application forms, further particulars of the post and information on pension, medical aid, group insurance, staff bursary, housing loan and subsidy schemes, long leave conditions and travelling expenses on first appointment are obtainable from the London Representative, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of Natal, PO Box 375, Pietermaritzburg, 3200, (telephone 63320), with whom applications must be lodged not later than 16 October 1981, quoting the reference PMB 51/81. (W407)A

UNIVERSITY OF OXFORD NUFFIELD DEPARTMENT OF ORTHOPAEDIC SURGERY MRC BONE RESEARCH LABORATORY

Applications are invited for two posts to work on the isolation and characterization of factors that induce the differentiation of bone cells.

(1) POSTDOCTORAL RESEARCH ASSISTANTSHIP

Starting salary (Range 1A) — £6,070 — £7,290 pa for biochemists with experience in protein isolation + cell culture techniques

(2) MEDICAL LABORATORY SCIENTIFIC OFFICER

Salary range — £4,851 — £5,334 for technical assistance with above project

The posts are supported by MRC for a three year period. Applications with full curriculum vitae and names and addresses of three referees to Dr J T Triffitt MRC Bone Research Laboratory, Nuffield Orthopaedic Centre, Oxford OX37LD, as soon as possible. (9367)A

FOR RESEARCH ON ANIMAL DISEASES

Scientific Research Position

International Laboratory for Research on Animal Diseases (ILRAD)

A vacancy exists in the Pathology Division of ILRAD for a Research Scientist to continue studies on the inductive mechanisms for cell-mediated immunity against the protozoan parasite *Theileria parva* in cattle and to analyse the antigenic composition of the parasite. Opportunities exist for collaborative research on surface markers of bovine lymphocytes and means of eliciting protective immunity against *Theileriosis*.

The applicant should possess a degree in Veterinary Science (or be familiar with experimentation in livestock) together with a PhD. Relevant postdoctoral experience would also be an advantage. Salary will be paid in US dollars according to experience. Perquisites include movement, housing and commutation allowances, medical and retirement benefits.

Applications with curriculum vitae and the names of three referees should be addressed to: The Director of Administration, ILRAD, PO Box 30709, Nairobi.

Closing Date: 15 September, 1981.

(W408)A

UNIVERSITY OF EDINBURGH DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH FELLOW

Crystallography

Applications are invited for the above SRC-funded post to investigate the crystal structures of some simple volatile inorganic compounds.

Applicants should have experience in X-Ray Crystallography. Familiarity with techniques of low temperature crystal preparation would be an advantage.

The appointment will be for two years starting on or after 1st January 1982. The initial placing will be on the 1A scale, starting at a point that will depend on age and qualifications.

Applications, including the names of two referees, should be sent to Professor E A V Ebsworth or Dr A J Welch, Department of Chemistry, University of Edinburgh, West Mains Road, Edinburgh EH9 3JJ, from whom further particulars may be obtained. Please quote reference 5049. (9428)A

Royal Postgraduate Medical School

(University of London)

Department of Clinical Pharmacology

SENIOR RESEARCH OFFICER (Post-Doctoral)

required to join a multi-disciplinary team involved in the characterisation of purified forms of human drug metabolising enzymes, in particular forms of cytochrome P-450. The successful applicant will have a PhD in Biochemistry, preferably with experience of protein chemistry. The post is sup-ported by the Medical Research Council until 31 August 1982. Salary on range IA between £6,070 - £7,700 plus £967 London Allowance a year. Applications forms and further details may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 20/458. (9419)A

Research opportunities with ELI LILLY

Eli Lilly and Company is one of the world's largest producers of clinical pharmaceuticals, animal health and agrochemical products.

At our U.K. Research Centre, situated near Camberley in Surrey, we are actively engaged in basic research on a variety of projects and we currently have three vacancies within our research teams.

PHARMACOLOGIST

An experienced pharmacologist (Ph.D or B.Sc.) with an interest in the immune system is required to participate in an inter-active programme exploring the pharmacology of cytokines and effector substances.

BIOCHEMICAL PHARMACOLOGIST

A recent graduate biochemist/pharmacologist is required in our Central Nervous System Research Group. This multidisciplinary group is primarily interested in the development of novel anti-psychotic drugs, and the successful candidate will be expected to continue existing projects and to initiate areas of novel research.

BIOLOGIST/IMMUNOLOGIST

A recent graduate (or H.N.C. equivalent) is required in our multi-disciplinary Immunology Research Group to work in areas of T-cell function, and antigen presentation and delayed-type hypersensitivity and to collaborate in hybridoma technology. Experience in tissue culture and/or various immunological techniques would be an advantage.

For all these positions, a highly competitive salary is offered together with a non-contributory pension and life assurance scheme, subsidised B.U.P.A., 21 days' holiday, flexible working hours and relocation expenses where applicable.

Please write to: Miss S.M. Smith, Personnel Manager.

LILLY RESEARCH CENTRE LIMITED

ERL WOOD MANOR, WINDLESHAM, SURREY. TEL: (0276) 73631

(9370)A

TISSUE IMMUNOLOGY SPECIALIST

for a senior post in Cape Town, perhaps the world's most attractive coastal city.

The Hospitals Department within the Cape of Good Hope's Privincial Administration seeks a Senior Specialist for the Tissue Immunology Laboratory, situated at the University of Cape Town Medical School.

This well established laboratory renders services to two major teaching hospitals, namely the Groote Schuur Hospital/University of Cape Town and Tygerberg Hospital/University of Stellenbosch (just outside Cape Town) as well as to the State Health Department.

Candidates should be experienced in all laboratory aspects of HLA typing and transplantation immunology. Knowledge of red cell serology and genetics would be a recommendation.

A fixed salary of R24,450 p.a. is offered (1 = R1.74) and, if necessary, the successful candidate will be assisted in finding accommodation. Cape Town itself offers comprehensive schooling and shopping facilities together with a high standard of living at low cost, some of the world's most attractive scenery, beaches and a Mediterranean-style climate.

Further details can be obtained from Dr. du Toit, Provincial Laboratory for Tissue Immunology, Private Bag 4, Observatory 7935, Cape Town, Republic of South Africa.

(9412)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London) Courtauld Institute of Biochemistry

POST-DOCTORAL RESEARCH ASSISTANT & RESEARCH ASSISTANT

Applications are invited for the above positions to work on an MRC supported project concerning the biosynthetic pathway of membrane proteins of the Golgi apparatus. The project will utilize a wide range of techniques including tissue culture, cell fractionation, cell-free protein synthesis and recombinant DNA technology. Previous experience in some of these techniques would be advantageous. Applicants should have a PhD or a good BSc Honours degree dependent on the position sought. The appointment three years from 1 October 1981 with a starting salary of £6,880 per annum plus £967 London Allowance (Postdoctoral Research Assistant) and £5,285 per annum plus £967 per annum London Allowance (Research Assistant).

Applications should be sent together with a curriculum vitae and the names of two referees to Dr R K Craig, Courtauld Institute of Biochemistry The Middlesex Hospital Medical School, London W1P 7PN.

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF PHYSIOLOGY AND ENVIRONMENTAL SCIENCES

POSTGRADUATE RESEARCH ASSISTANT

Applications are prited for the above ARC funded post to investigate the role of cell wall degrading enzymes during abscission. The post is for a period of 3 years and suitable candidates may register for a higher degree.

Applicants should have a good honours degree in a biological science and should send a Curriculum Vitae, together with the names of two referees to: Dr J A Roberts, Department of Physiology and Environmental Sciences, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough LE12 5RD. (9426)A

PROJECT MANAGER (PM) TEN METER TELESCOPE (TMT) UNIVERSITY OF CALIFORNIA (UC)

Applications are invited for the current opening of project manager for the UC TMT. The PM will have overall project responsibility for planning, engineering design, cost estimation, scheduling, and budget management for procurement, fabrication, and construction during the design and construction phases of the Ten Meter Telescope and related facilities. The PM will work in close cooperation with the project scientist in the determination of design and performance specifications and the development of the detailed engineering design. Applicants should have demonstrated ability to complete major projects on time within budget. Experience in siting and site support requirements of standalone research facilities is valuable. Knowledge of electromechanicaloptical systems, computer environments, structural engineering, and laboratory research facility designs is desirable. Experience as manager of major research construction projects is a requirement. Applicants with degrees in engineering or physical sciences are preferred.

The PM will be an associate director of Lick Observatory reporting to a UC Executive Management Committee. Salary will be commensurate with experience and qualifications.

Applicants should send résumé and the names of three persons who have been asked by the applicant to submit letters of professional reference directly to the Chair. All application materials should be received by 15 September 1981 and should be sent to:

Dr. Harold Ticho TMT/ENC Chair c/o Lick Observatory University of California Santa Cruz, California 95064

An Equal Opportunity/Affirmative Action Employer (NW836)A

RESEARCH ASSOCIATE and

POSTDOCTORAL FELLOWS

Positions immediately available to investigate monoclonal phagocyte biology as part of an active research group devoted to this area. Emphasis on monoclonal antibodies as probes of function and differentiation. PhD in immunology, biochemistry or pharmacology preferred. Salary commensurate with experience.

Send curriculum vitae and three references to: Dr Stephen W Russell, Director, Comparative and Experimental Pathology, Box J-145, JHMHC, University of Florida, Gainesville, FL 32610. Closing deadline for applications is 15 October, 1981. The University of Florida is an equal opportunity/affirmative action employer. (NW838)A

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts AL5 2JQ PLANT PROTOPLASTS

Applications are invited from graduate biologists to join a team working in the Biochemistry Department on the genetic manipulation of crop plants. The successful applicant will be expected to develop techniques for the regeneration of crop plants from isolated protoplasts. Applicants must have a proven record of success in plant regeneration and protoplast technology and preference will be given to those with a PhD and some post-doctoral experience.

Qualifications: 1st or Upper 2nd class honours degree.

The successful applicant will be appointed in one of the following grades according to qualifications and experience: Higher Scientific Officer (£6,075 — £7,999); Senior Scientific Officer (£7,644 — £9,619); Principal Scientific Officer (£9,690 — £12,540).

At least 2 years relevant experience is required for HSO grading, and 4 years for SSO. Grading at PSO level will only be considered for exceptional candidates. Pay award pending. Non-contributory superannuation.

Apply in writing to the Secretary naming two referees and quoting Ref. 459 by 19th September 1981. Further details on request.

(X9326)A

DURHAM UNIVERSITY CHEMISTRY DEPARTMENT Reactivity of Nitrous Acid Scavengers

Applications are invited for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

for one year to study the kinetics of nitrosation using fast reaction techniques under the direction of Dr D L H Williams.

Initial salary in the range £6,070 to £6,880 on Range IA plus superannuation.

PHYCHOLOGY DEPARTMENT

Applications are invited from graduates in psychology or other biological subjects for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANT IN PSYCHOLOGY

for one year from 1 October or as soon as possible thereafter to work on reproductive behaviour with Dr R F Drewett.

Salary up to £7,700 on Range IA plus superannuation.

For both posts, applications (3 copies) naming three referees should be sent to the Registrar, Science Laboratories, South Road, Durham DH1 3LE by 21 September 1981, from whom further particulars may be obtained. (9401)A

INVERESK RESEARCH INTERNATIONAL

SENIOR APPOINTMENTS IN BIOTECHNOLOGY

IRI, a leading company in the contract biomedical research field, is expanding into the area of application of monoclonal antibody technology and genetic manipulation to problems of industrial and medical interest. Applications are therefore invited from scientists interested in applied contract research, both positions are at senior level and will provide ideal opportunities for imaginative scientists to become involved in the scientific and policy developments in the following areas:

MONOCLONAL ANTIBODY TECHNOLOGY

Applicants should have post-graduate experience in immunology and/or tissue culture, preferably with direct experience of hybridoma technology. (Ref. 1701).

GENETIC MANIPULATION

Applicants should have post-doctoral experience in plasmid manipulation and/or expression of foreign genes. (Ref. 1702).

Salaries reflecting the seniority of the posts will be on an incremental scale system, with placement according to relevant experience. Benefits include an excellent pension and life assurance plan, BUPA and relocation assistance if required. IRI is situated in a pleasant rural area within easy reach of Edinburgh and the surrounding country.

Application forms, quoting the appropriate reference, are available from the Personnel Department, Inveresk Research International Limited, Musselburgh EH217UB. (9406)A

UNIVERSITY COLLEGE DUBLIN

DEPARTMENT OF PHARMACOLOGY

A temporary one-year vacancy exists for the 1981/82 session in the Department of Pharmacology at

ASSISTANT LECTURER OR COLLEGE LECTURER LEVEL

Applications are invited from candidates with:

didates with:

(a) an appropriate honours primary degree and

(b) PhD, (except in the case of medically qualified candidates).

The current salary scales are: Assistant Lecturer: Ir£6,839 — £10,933. College Lecturer: Ir£10,572 —£14,556.

Entry point on the relevant scale will be in accordance with qualifications and experience.

Prior to application details of application procedure should be obtained from the Secretary and Bursar, University College, Belfield, Dublin 4. Telephone enquiries: 693244 ext 431.

The latest date for receipt of completed applications is Thursday, 17th September 1981. (9425)A

ST THOMAS' HOSPITAL MEDICAL SCHOOL

DEPARTMENT OF HISTOPATHOLOGY

London SE1 7EH

BIOCHEMIST

With a good honours degree in Biochemistry or a related subject, to work on a project involving the immunocytochemical localisation of lung tumour markers.

The appointment will be for One year in the first instance.

The work will include protein purification techniques; affinity and gel chromatography. ELISA and radioimmunoassay of a variety of antigens and antibodies and quantitation of immunocytochemical results. This appointment would suit someone wishing to write a PhD thesis or a post doctoral scientist, and will be carried out in the department of Histopathology. The emphasis of the work will be on the clinical application of the techniques.

Salary up to £7,110+Londen Weighting depending on age and experience.

Apply in writing with the names of 2 referees to Dr E Heyderman, REF BC, Department of Histopathology, St Thomas' Hospital Medical School SE1 7EH by Sept 11th 1981.

(9407)A

Assistant Professor of Pharmacology/ Division of Neuropsychopharmacology

The Department of Pharmacology at The Medical College of Pennsylvania invites applications for a full time appointment within the Division of Neuropsychopharmacology as a Behavioral Physiologist or Psychopharmacologist. Applicants should have a PhD or equivalent degree with at least 2 years post doctoral experience. This position requires an individual to set up his/her own research program and also collaborate with other individuals in basic neurochemistry and clinical psychopharmacology. Submit curriculum vitae and references to:

Benjamin Weiss, PhD Director, Division Of Neuropsychopharmacology

MEDICAL COLLEGE OF PENNSYLVANIA

Department of Pharmacology 3300 Henry Avenue Philadelphia, Pa. 19129

An Equal Opportunity Employer, M/F

(NW835)A

MEDICAL LABORATORY SCIENTIFIC OFFICER

Required to work on projects involving radioimmunoassay to determine the antibody responses in patients allergic to food. Only one year left on the grant. Salary on Whitley Council Scale according to qualifications and experience.

Applications in writing, enclosing ev and the names of two referees to: Dr J Brostoff, Department of Immunology, The Middlesex Hospital Medical School, Arthur Stanley House, 40-50 Tottenham Street, London W1P9PG. (9418)A

MEDICAL LABORATORY SCIENTIFIC OFFICER

(Locum for seven months)

to do assays for parathyroid hormone for Regional Assay Service. Present encumbent on Maternity Leave. Interesting work in modern laboratories. Previous radio-immunoassay experience desirable.

Applications in writing to Dr J L H O'Riordan, Department of Medicine, The Middlesex Hospital Medical School, London W1P 7PN. (9417)A

Research Associate in Biochemistry

To collaborate in the Department of Biochemistry of the Kirksville College of Osteopathic Medicine on research into the biochemical basis of experimental epilepsy by the measurement of structural and functional changes in brain synaptosomal membranes. The work will involve measuring uptake of biogenic amines and cations by brain synaptosomes; assessing synaptosomal membrane structure using fluorescence probes and assessing changes in lipid domians of key synaptosomal enzymes. Applicant must have a PhD in biochemistry, 2 or more years postdoctoral research experience, some background in membrane biochemistry and familiarity with methods in lipid biochemistry, electrophoresis, chromatography, enzymology and spectrophotometry. Excellent working conditions with air-conditioned research laboratory, 40 hours per week. Salary \$17,000 per year.

Please send résumé (order 549641) to: Kirksville Job Service, 310 N. Elson, Kirksville, MO 63501.

Applicant must be legally qualified to accept U.S. employment. Equal Opportunity/Affirmative Action Employer M/F/H. (NW839)A

UNIVERSITY OF CAMBRIDGE PHYSIOLOGICAL LABORATORY

Applications are invited for a

GRADUATE RESEARCH ASSISTANT

to work on the molecular mechanism of voltage gating in the sodium channel. Applicants should have a First Class Honours Degree in physics or biophysics, and some experience of computer programming. Salary on range 1A scale, starting point up to a maximum of £6,880 per annum, with placing according to age.

The post will be tenable for 3 years from 1 October 1981. Further particulars may be obtained from Professor R D Keynes FRS with whom applications should be lodged by 15 September 1981. (9421)A

LABORATORY Scientific Officer required for two years to join a team using new techniques to study mammalian organogenesis/gametogenesis. Histological proficiency essential. Apply is writing to the Administrative Assistant, Paediatric Research Unit, Guy's Hospital Medical School, Guy's Tower, London Bridge SE1 9RT. (9395)A

MRC MEDICAL RESEARCH

COUNCIL

Clinical Oncology and Radiotherapeutics Unit

Applications are invited for this NON-CLINICAL SCIENTIFIC

post which may be filled by either a Short-Term appointment of 3(to 5) years or a Career appointment according to the age and experience of the successful candidate. A Career appointment will be tenable at this unit in the first instance. The person appointed will join a multidisciplinary research team directed towards the improvement of clinical cancer therapy. This appointment is for a scientist with experience in some aspect of mammalian cell biology who will develop his/her own research interest within the context of the unit's work. It is anticipated that the successful candidate will also participate in ongoing collaborative studies with experimental human tumour systems. Remuneration will be at an appropriate point on the scales for university non-clinical academic staff.

Further information and an application form may be obtained from The Administrator, MRC Centre, University Medical School, Hills Road, Cambridge CB2 2QH with whom applications — including a full CV and the names of 2 professional referees — should be lodged within two weeks quoting reference number CO/5. (9400)A

RESEARCH ASSOCIATE (PROTOZOOLOGY/TISSUE CULTURE)

CENTRE FOR TROPICAL VETERINARY MEDICINE University of Edinburgh

Applications are invited from honours graduates in biological sciences with an interest and research experience in parasitology for the position of Research Associate in the Protozoology Section of the Centre for Tropical Veterinary Medicine.

The person appointed will be expected to work within a group studying the characteristics of African pathogenic trypanosomes and would be primarily concerned with the growth of these parasites in arthropod and mammalian tissue culture.

The appointment will be on contract, starting as soon as possible. The length of contract will be subject to the continuing provision of funds by the Overseas Development Administration. Salary, according to experience, will be in the range £6,070 to £8,925.

Application by letter giving a full curriculum vitae, stressing post graduate research experience and interests and including the names of two referees, should be addressed to the Director, CTVM, Veterinary Field Station, Easter Bush, Roslin EH25 9RG, Scotland. (9411)A

SOUTH HAMMERSMITH HEALTH DISTRICT West London Hospital JUNIOR 'B' MEDICAL LABORATORY SCIENTIFIC **OFFICER**

We wish to appoint an Immunology/ Biochemistry graduate to work in Obstetrics and Gynaecology at West London Hospital, Hammersmith Road, London W6.

This post is of a fixed term nature for one year only in the first instance, from 1st October, 1981 and will involve assisting with a project on "Development of monoclonal antibodies for immunoassay of human placental alkaline phosphatase in normal and abnormal pregnancy".

Inclusive salary scale: £3,470 -£4,631 (under review).

Applicants wishing to discuss the post informally should contact Dr SF Contractor, 01-748 3441 ext 127, after 1st September, 1981.

For an application form and job description, please contact the District Personnel Department, on 01-748 2040 ext 2992. (9399)A

THE EUROPEAN MOLECULAR **BIOLOGY LABORATORY**

in Heidelberg, Germany, invites applications for a post in the Biological Structures Division as

RESEARCH TECNICIAN

The successful applicant will work on the purification and crystallisation of proteins in a group headed by Professor Demetrius Tsernoglou. Experience in the fields of protein chemistry or crystallography would be advantageous, but a good general background with possibly a technical or scientific qualification, is more

Net salary after tax will be between DM 2,600 and DM 2,900 monthly, in addition to which certain allowances are payable, depending on personal circumstances. Initial contract of 3 years' duration and financial assistance with relocation.

Please contact EMBL, Personnel Section, Postfach 10.2209, D - 6900 Heidelberg, Germany, quoting reference 81/15, for (W406)A an application form.

IMPERIAL CANCER RESEARCH FUND TECHNICIAN/RESEARCH **OFFICER**

Required in our Cytogenetics Laboratory to analyse and identify the human chromosomes in human/ mouse somatic cell hybrids and analyse some human tumour material. Experience in human cytogenetics essential.

Degree/HNC Salary range £5,637 to £7,881. For further information and application form write or tele-phone to Miss S. M. Hurley, Imperial Cancer Reseach Fund, Lincoln's Inn Fields WC2 on 242 0200 ext 305, quoting ref 137/81. (9424)A

PUBLIC HEALTH LABORATORY SERVICE BOARD

PATHOGENIC MICROBES RESEARCH LABORATORY

A graduate, or well-qualified MLSO or Junior 'B' MLSO is required to assist in a study of the growth and metabolism of bacterial populations implicated in the pathogenesis of dental caries. The project will involve the use of continuous culture techniques. The appointment, sponsored by

the Medical Research Council, will be for up to two years and in the salary range £2,943 - £6,597.

Further details of the post can be obtained from Dr P D Marsh, Tel: 0980-610391

The appointment will be either at MLSO or Junior 'B' MLSO, depending on age, experience and qualifications.

Applications, including curriculum vitae and the names and addresses of two referees, should be sent to Mrs M Bushby, Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts.

Closing date for applications 18th September 1981. (9396)A

DEVON AREA HEALTH AUTHORITY **Exeter Health Care District**

SENIOR PHYSICIST (£7,574 - £9,921 pa) (pay award pending)

The Department of Urodymanics/ Sphincter Unit (Physics Service) based at the 7 year old Royal Devon and Exeter Hospital (Wonford), provides an investigative and diagnostic service to referring Consultants. A Senior Physicist is required to assist the Scientific Director in this work, which deals with urological disorders, and to expand the service of other fields including oesophageal investiga-

Candidates must have considerable interest in this type of applied clinical science and the ability not only to integrate well with staff of various disciplines but also to communicate effectively with patients Opportunities will exist for introducing new techniques and for developing instrumentation for diagnostic and therapeutic purposes. Training in the techniques of conducting urodynamic investigations and interpreting relevant data will be provided.

The Unit, which has close links with the Medical Physics Group at the University of Exeter, is housed in purpose-built, well-equipped

accommodation.

Candidates with a degree or equivalent qualifications, appropriate experience with a good background in electronics and a genuine interest in patient care are invited to obtain the application form and job description of this new and challenging appointment from the Personnel Officer, Royal Devon and Exeter Hospital (Wonford), and Exerer Hospital (Wontord), Barrack Road, Exeter EX2 5DW, tel Exeter (0392) 77833 ext 2188, or contact Dr E D James, Scientific Director ext 2278 for further details. ANNOUNCEMENTS

BAYLISS & STARLING SOCIETY NATIONAL SCIENTIFIC MEETING 18th — 19th DECEMBER 1981 **ROYAL POSTGRADUATE MEDICAL SCHOOL,** LONDON

A two-day programme of submitted platform presentations and posters on the topic of

Regulatory Peptides and **Gut Hormones**

To bring together all the workers in this currently disparate field, Anatomists, Biochemists, Biologists, Physicians, Physiologists, Veterinarians, etc - All Welcome

Invited Address by

Prof. Viktor Mutt

Abstract Deadline: Receipt before 27th October

(Abstracts to be published in Regulatory Peptides)

For Abstract forms and further information on low cost accommodation etc write to: Dr. S. R. Bloom/Dr. J. M. Polak Hammersmith Hospital Du Cane Road London W12 0HS

The Bayliss & Starling Society is a Registered Charity (No. 279143)

> Council Members: S. R. Bloom, J. M. Polak, Sir F. Avery Jones, J. H. Baron, J. C. D. Hickson,

G. J. Dockray, K. D. Buchanan.

R. A. Gregory.

STUDENTSHIPS

UNIVERSITY OF READING

DEPARTMENT OF AGRICULTURE AND HORTICULTURE

POSTGRADUATE STUDENTSHIPS RABBIT NUTRITION

Applications are invited for two studentships available in the Department of Agriculture and Horticulture for research leading to a PhD degree. The studentships are provided by the Tropical Products Institute under conditions comparable with the Science and Engineering Research Council scholarships and are for work on (1) the protein and amino acid requirements of rabbits and (2) determination of the metabolisable energy content of feedstuffs and development of methods of estimating ME for rabbit feed from chemical composition.

Applications from graduates with First Class or Upper Second Class Honours degrees in Biological Sciences or Agriculture giving details f academic training and experience and names and addresses of two cademic referees should be sent to or T R Morris, Department of Agriculture and Horticulture, University of Reading, Earley Gate, Reading RG6 2AH. A selected list of candidates will be invited to attend for interview on 29 September 1981. (9405)F

FELLOWSHIPS

THE OPEN UNIVERSITY Faculty of **Mathematics**

Research Fellowship in Applied **Mathematics**

Applications are invited for a research fellow post (funded by the Science Research Council) to work on semi-classical theories of molecular scattering. Can-didates should have a PhD in mathematics or physics and should have some knowledge of classical dynamics and semiclassical theories.

Appointment will be made at an appropriate point on the Research Fellow scale (£6,070 £10,575), but not exceeding £6.880 at the highest point. The post is for two years and is available from 1st October 1981. Application forms and further particulars may be obtained from Ms R L Johnson, (4236/2), Assistant Secretary (Maths), The Open University, Milton Keynes MK7 6AA or telephone Milton Keynes 653784: there is a 24 hour answering service on 653868.

Closing date for applications: (9416)E 10th September.

Training Fellowships in Human Nutrition

The Medical Research Council and the Agricultural Research Council wish to increase the cadre of research workers with training in subjects relevant to human nutrition, particularly in areas suitable for collaboration between the Councils.

Applications are invited from clinicians or postdoctoral non-clinical scientists for MRC training fellowships. Details of the areas of work being encouraged are available, but applications will be considered in any modern aspects of human nutrition and the underlying sciences. The followships will be available for a programme of research training divided between an MRC supported establishment or university department and a similar ARC supported group. Tenure will be for any period from six months to three years.

Application forms, closing dates and further details may be obtained from Training Awards Group, Medical Research Council, 20 Park Crescent, London W1N 4AL. (Telephone 01-636 5422 ext 448). Medical Research Council

ASSISTANTSHIPS

UMIST DEPARTMENT OF **BIOCHEMISTRY Agricultural Research Council Group in Lignin** Biodegradation Ref: BIO/117/AI

Applications are invited for two RESEARCH ASSISTANTSHIPS

The team (7 members) is supported by the ARC and by British Petroleum's Venture Research Unit, and is in completely new and well equipped laboratories. Applicants should have at least a good Honours degree and postgraduate experience or a PhD in microbial physiology, biochemistry, mole-cular biology or a related subject. Appointments are for up to 3 years in the first instance, with a possibility of extension, and will commence as soon as possible. Further information can be obtained by contacting Professor P Broda (tel: 061-236 3311 ext 2119). Salaries will be within a range up to £9,335 per annum.

Requests for application forms, quoting the above reference, should be addressed to the Registrar, Room B6, UMIST, PO Box 88, Manchester M60 1QD. The closing date is 18 September 1981. (9410)P

UNIVERSITY OF OXFORD **Dyson Perrins** (Organic Chemistry) Laboratory

Applications are invited from suitably qualified

ORGANIC CHEMISTS for a postdoctoral research assistantship to work on the synthesis of reversible oxygen carriers. The appointment, in Grade 1A, supported by BP would be for one year from October 1981, at a salary within the range £6,070 to £6,880 p.a. (according to age and experience) plus USS.

Applications, quoting Reference R81/3, with curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to Professor J E Baldwin, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY. (9413)P

UNIVERSITY OF LEICESTER

DEPARTMENT OF ZOOLOGY

RESEARCH **ASSISTANTSHIP**

Applications are invited for the post of Research Assistant at post-doctoral or graduate level to join a group working on the arrangement and expression of DNA sequences in the chromosomes of amphibians.
Applicants should have some experience with recombinant DNA and related technologies. The appointment will be for one year in the first instance, commencing 1st October, 1981, but is likely to be renewable for a further 2 or 3 years. Salary scale £5,285 to £7,700.

Applications, with the names of 2 academic referees, to Professor H C Macgregor, Zoology Department, University of Beicester, Leicester LE1 7RH. Enquiries by telephone welcome (0533-55465 ext 113).

DURHAM UNIVERSITY BOTANY DEPARTMENT

Applications are invited for a

POSTDOCTORAL SENIOR RESEARCH ASSISTANTSHIP

from suitably qualified cell biologists to work on aspects of crop improvement using recombinant DNA methods. The post is tenable for up to 3 years from 1 October 1981 or as soon as possible thereafter. Experience in plant cell, protoplast or tissue culturing methods preferred.

Salary on 1A Scale plus superannuation.

Applications (3 copies) naming three referees to be sent by 11 September 1981 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained.

Definitive, Complete, Authoritative

NATURE announces the publication in 1981 of the Annual Directory of Biologicals and Disposable Chemicals. The directory will be available for distribution to all NATURE subscribers in the Autumn of 1981. It will also be marketed separately, offering an even larger distribution.

A New Buyers guide

The basic thrust of the directory will be to provide NATURE subscribers with a definitive reference catalogue from which they may purchase the chemicals and disposables listed.

From research conducted around the world the NATURE marketing staff has determined the need for a directory of biologicals, disposable chemicals and gases. Probably more than any other scientist, the NATURE reader represents the largest potential market for the sale of these chemicals.

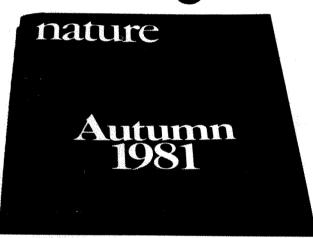

very attémpt will be

made to produce a catalogue that will reference the worldwide market of chemical manufacturers, distributors, suppliers, and exporters.

No instrumentation or apparatus listings will be included in this directory; its sole purpose is to provide detailed information for our readers as to where they may secure the biologicals, chemicals and gases for use in their

laboratories.
The directory will be cross-referenced and include chemical classifications, product classifications, geographical location of suppliers and other referenced information as needed.

NATURE Directory of Biologicals

What's in It?

The directory will include (but not be limited to) these biological reseach chemicals

- mmunochemicals
 - cell lines
 - fine chemicals
 - reagents
 - enzymes
 - isotopes
 - monoclonals
 - ases, etc.
